

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### **Usage guidelines**

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### **About Google Book Search**

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

## Original Communications.

### CASE OF SUPPURATING OVARIAN CYST COMPLICATED BY THE EXISTENCE OF A DEEPLY-SEATED PELVIC ABSCESS.

By LOMBE ATTHILL, M.D.,  
Ex-Master of the Rotunda Hospital.

On the 26th Nov., 1884, a lady came to town to undergo the operation of ovariectomy. She was sent to me by Dr. Moran, of Gort, who had previously diagnosed the existence of an ovarian tumour.

On examination I was satisfied that the tumour consisted mainly of one large cyst, but there was also a solid portion which lay in the left inguinal region. The case seemed a favourable one for operation, and as the patient was very anxious to have the tumour removed, I decided to operate at once; but a sharp attack of bronchitis, the result of cold caught during her journey, supervening, the operation was necessarily postponed. On the bronchitis subsiding, she was attacked with peritonitis, which required the application of leeches and the free exhibition of opium. The fever was high, and there was much pain.

As these symptoms subsided I was much disappointed to find that her condition did not improve as I had hoped, and I now observed a new phase in her illness; hitherto, the temperature had ranged from 101 deg. to 102 deg., now at night it rose to 103.5, to fall to 98 deg. in the morning, the pulse ranging from 140 to 120 in the minute; the tongue too became dry and glazed, and I came to the conclusion that the contents of the tumour must be undergoing a change.

Dec. 21st.—Her condition now was most unsatisfactory, and indeed alarming, her illness had lasted four weeks. She was very feeble and greatly emaciated, the pulse small and rapid, the temperature, as already stated, varying 5 deg. between night and morning. The urine was very scanty and high coloured, only eight ounces

being secreted in 24 hours. There was great thirst, and any attempt to take food other than milk and soda-water, or beef tea, was followed by vomiting, in fact, nothing could be more unfavourable than her condition for the performance of a capital operation. It was evident, however, that in the condition the patient was in she could not long survive, and that the only hope of saving her life rested on the speedy removal of the tumour. The patient willingly agreed to undergo the risk, and was operated on the morning of the 23rd of Dec. Ether was administered by Dr. Charles Ball, and I was assisted by Professor Stokes. The atmosphere in the room was thoroughly impregnated with carbolic spray, but it was not allowed to play on the abdomen, all other antiseptic precautions were strictly observed.

The first part of the operation presented no difficulty. The large cyst was rapidly exposed and emptied. There was nothing exceptional in the fluid contained in the large cyst, but on proceeding to break down the small cysts which composed the more solid portion of the tumour, they were found to contain pus. The diagnosis that the cyst was a suppurating one was therefore verified.

But although the cyst was thoroughly emptied of its contents, it could not be drawn forward, and I now found that its base was intimately adherent to the pelvic walls, both laterally and posteriorly. The task of breaking down the adhesions was tedious and difficult, those to the right were first separated, then those posteriorly, but while breaking down those to the left, at a point corresponding to the solid portion of the tumour, in which were situated the suppurating cysts, I was disagreeably surprised at finding a quantity of by no means inodorous pus to well up. At the moment I assumed that I had torn the wall of the cyst, and that the pus had been contained within it, and it was not till some time after the operation was over, that I discovered, on a careful examination of the tumour, that it had been removed in perfect condition. The pus, therefore, must have come from a deeply-seated pelvic abscess.

The base of the tumour was at length freed from its

attachments, drawn forward and separated. The pelvis was now full of blood and pus, which was carefully removed, and the cavity washed out with a five per cent. solution of carbolic acid.

Blood, however, continued to ooze freely from the torn surfaces, and pressure by means of sponges had to be made on them for a short time, before it was arrested. The wound was then closed, but I deemed it wise to insert a drainage tube. My reasons for doing so being, the oozing of blood had not absolutely ceased, and also because a large quantity of pus having escaped into the pelvis the danger of septic poisoning was greatly increased. The result fully justified this step.

The patient was in a state of extreme collapse at the termination of so tedious an operation, but she soon rallied, and in 2 hours complete reaction was established.

At 3 p.m. the temperature was 102 deg. at 10 p.m. it had fallen to 99.6 deg., pulse 130; there was no vomiting, and the urine, which had been very scanty for some days previously, was not freely secreted, little pain was experienced. A quantity of serous fluid escaped from the drainage tube, and at 10 p.m. I removed through it, by means of a syringe, nearly twelve ounces of bloody fluid which fell rapidly a copious deposit consisting mainly of blood and pus corpuscles. The fluid thus removed had a very heavy sickening smell. The patient past a very quiet but sleepless night.

During the next day all went on well. The temperature did not rise above 100 deg., the pulse, however, was feeble, and 130 in the minute. About three ounces of fluid similar to that removed the previous day was sucked out through the drainage tube.

On the morning of her fourth day (the 26th Dec.) her state was so satisfactory, and such a small quantity of fluid could be withdrawn from the tube, that I removed it, laying a fold of carbolic gauze over the place it had occupied in the abdominal wall, but on visiting her at 10 p.m. that night, I found matters altered for the worse, the temperature had risen to 102 deg., and the pulse to 130. I at once decided to reopen the communication with the cavity of the abdomen, but instead of again inserting the drainage tube, I passed into the pelvis a No. 12 gum elastic catheter, attached to an exhausted rubber bag and sucked out six oz. of fluid of similar character to that previously removed, but with a much more feculent odour.

27th.—She had a very restless night, but the temperature fell to 100 deg., the tongue had again become dry and glazed, there was no pain or tympany, and flatus was passed per anum. I again introduced the catheter and removed a couple of ounces of foetid fluid, so foetid that I at once decided on washing out the cavity with a disinfecting lotion, and with this view injected several ounces of carbolic solution of the strength of about 5 grains to the ounce, and this was repeated twice daily till the 2nd of January, when I substituted for it a solution of the permanganate of potash.

For several days subsequently her condition remained unchanged. On the 28th the bowels were moved by an enema, and a large quantity of flatus passed; there was not the slightest symptom of peritonitis, but the pulse continued small and rapid, 120 to 130 in the minute, and the temperature ranged from 100 deg. in the morning to 102 deg. at night. The tongue was dry and glazed, and there was much thirst.

On the 29th I was obliged to place her on a water bed, being apprehensive of bed sores forming. The fluid removed from the abdomen became less in quantity, but more and more like pus, and at the same time more foetid, and about the 31st (that is the 9th day) could not be distinguished from the pus met with in abscesses formed in close proximity to the rectum. I have seldom indeed met with more markedly foetid pus.

During all this time, and up to the 14th day (that is the 6th Jan.) she had taken nothing but beef tea, or soda water and milk, one ounce of one or other being also given every alternate hour; but on the 6th her

tongue had become so moist and clean that I allowed her a little bread and butter with a cup of tea, this she enjoyed very much, and I considered all danger over, it being the fifteenth day since the operation. The bowels had moved without discomfort every second day during the previous week, an enema of tepid water being given to assist their action. Judge then of my disappointment on being hastily summoned at noon on that day, to find that fecal matter was being discharged through the opening in the abdominal wall. The nurse was in the act of administering the enema, and had only injected about 8 ounces of water, when the patient called out that the fluid was coming through the opening in the abdomen, and so it was, and it was evident that the wall of the intestine had softened and given way. That the opening was valvular was proved by the fact that though fecal matter passed into the pelvic cavity, no pus passed the reverse way, namely, from the pelvic cavity into the rectum.

From the date of this unfortunate occurrence, namely 8th Jan., the patient's recovery was steady, but very slow. Of course the exhibition of enemata had to be discontinued, and, as the patient absolutely refused to take pills, it was a matter of difficulty to get the bowels to act satisfactorily. When the motions were solid no fecal matter passed through the fistulous opening in the abdominal wall, but if they were liquid more or less always did so. As the opening in the abdominal wall showed a great tendency to contract, I inserted a short piece of vulcanite drainage tube, which the patient was taught to remove and cleanse daily.

After the lapse of a few weeks the patient was well enough to travel to the West of Ireland, and I saw her on her way through town on the 10th of May. During the interval she had greatly improved. She had gained flesh, looked healthy, and was able to take a little outdoor exercise daily. She still wore the drainage tube, and occasionally a small quantity of fecal matter was voided through, but for several days together this was absent, and the bowels acted with tolerable regularity. It is therefore evident that the opening in the wall of the intestine is closing, and there is, I think, good reason to hope that this lady will recover perfectly.

The operation in this case was undertaken as a last resource, under the most unfavourable circumstances. The diagnosis of suppurating cyst was verified, but the existence of a deeply-seated pelvic abscess was not suspected, indeed I do not see how it could have been diagnosed, as the size of the tumour rendered an exploration of the pelvic cavity impossible. The occurrence of the recto-pelvic fistula was probably due to the fact that the wall of the intestine was in contact with the abscess and had become softened as the result of the inflammation which had been set up in its vicinity, and possibly in which it had been implicated.

P.S.—Since this paper went to press I have received a letter from my patient, stating that there had been no fecal discharge for some time, and this even though she had suffered from diarrhoea for several days. This points to the conclusion that the communication with the intestine has closed. I have therefore directed her to withdraw the drainage tube, and allow the opening in the abdominal wall to heal up.

## INFLUENCE OF SEA-VOYAGING UPON THE GENITO-UTERINE FUNCTIONS.

By J. A. IRWIN, M.A. Cantab., M.D. Dub. Univ.,  
Formerly Physician to the Manchester Southern Hospital for Women and Children.

(Concluded from page 557.)

SINCE it has been shown that the sea influence is of a distinctly stimulating character to the ovario-uterine organisation, it may fairly be supposed that a voyage soon before the natural advent of puberty would hasten that event. My opportunities of direct observation have

been too limited to throw much light upon this matter, as only on two occasions was I certain of first menstruations occurring on ship-board; although at other times I have suspected that such might be the case when circumstances did not favour a positive knowledge. A careful inquiry among those of wider experience confirms the belief that this incident is by no means infrequent during the Transatlantic passage; and it seems probable that the same may happen soon after landing, hastened by the voyage. The point acquires a local interest from the fact that it is during the late spring and early summer that American girls usually cross the ocean for the first time, at which season of the year, according to Emmet (21) and others, the organs of generation are most active, and first menstruations most frequently take place.

Turning to the other extreme of menstrual life, it is easily understood that an unwonted pelvic vascularity should disturb a process which, although normal, is essentially one of decadence of nutrition and degeneration of tissue. I have had under observation, at sea, three women at the climacteric epoch. On each occasion a hæmorrhage occurred during the voyage, and exceeded anything previously experienced by these patients. Dr. Brice and others have seen many similar instances. Dr. Exham, of the *City of Berlin*, tells me of a remarkable case which occurred in his practice scarce two months since: A lady, aged forty-five, who had not menstruated for over three years, and was free from local disease, became extremely sea-sick soon after embarkation, and on the fourth day of the voyage was attacked by a profuse and obstinate menorrhagia. As already stated, I have failed to establish any necessary connection between kinetia and menstrual disturbances. Cases such as Exham's, however, suggest a reflection, which at an appropriate moment might be worthy of consideration. Many observers of sea-sickness have compared its severer forms to the collapse stage of cholera, during which it has been noticed that a sanguineous discharge from the uterus is by no means uncommon. (22) Can it be possible that not only does the vomiting of kinetia irritate and congest the uterine organisation, but further, by its rapidly exhausting influence, rob the vessels of the tone necessary to resist the increased stress put upon them? Upon both sexes, but more especially upon the female, the aphrodisiac influence of the life afloat may be accepted as a traditionally established fact. To test its universality or estimate its degree would be a manifestly difficult task; nor can it be deemed important, since the introduction of steam has so materially abridged the duration of ocean voyages. It is easily understood how an increased blood-supply to the genito-uterine organs should stimulate sexual instinct; there are, however, on ship-board a variety of coincident circumstances all tending in the same direction: the mentally soothing influence of the sea, the invigorating air, the highly spiced nature of the food, the close and constant proximity of the sexes, the relaxation of social restraints, the indolence of the life, and lastly, a universal idleness—"the mother of mischief." Dr. Brice mentions the case of a lady whose life was exemplary, and who had reached the menopause, but who found herself constantly tormented with amorous dreams every night while at sea. The distinction of cases likely to be benefited by a voyage from those in which there would be danger of positive injury follows almost as corollary upon the views already expressed.

An ocean voyage should be regarded as a *potent emmenagogue*, having, in addition to this special quality, a well-marked tonic, alterative, and sedative influence. With this character it is entitled to head the list of therapeutic agents of similar effect, and should no longer be prescribed empirically, but, as they are, with a definite object in view. There are many cases in which these local and constitutional properties are especially indicated, and in which they may be jointly utilised with excellent results—in the conditions included under the term chloro-æmæmia; in amenorrhœa dependent upon deficient tone, or an undeveloped state of the organs; in retarded sexual

maturity; in certain forms of leucorrhœa, uterine asthenia, and sterility; and above all, in those delicate, gawky, over-schooled girls in whom abeyance of uterine function is often among the first warnings of approaching phthisis.

Dr. Emmet (23) mentions an interesting case which may be taken as typical of the entire class: A young lady in whom, as a consequence of over-study, the menses became scanty and irregular, and finally suppressed entirely toward the close of the first year of menstrual life. For three years she travelled about, but with no return of the menstrual flow, except when the period was passed at sea. It was finally arranged, as a part of the treatment, that she should sail a day or two before the period during several successive months, with the effect on each occasion of inducing the natural flow. The same satisfactory result and concomitant improvement in general health may, I am satisfied, be confidently expected in every similar case. It will of course be understood that, upon a large majority of the women who cross the ocean the sea influence is too slight and too transient to be considered of serious import. There are, however, many conditions of the uterine organism which, if not positively interdicting a voyage, at least demand careful prophylaxis, and skilled attention while on board. I have arrived at the somewhat general conclusion, which, however, I express subject to the dictum of future investigation, that almost every form of uterine and ovarian disease becomes worse while at sea. Gynecologists are aware that the menstrual period is usually a time of retrogression. It has appeared to me that a sea-voyage, and more especially the turbulent Atlantic transit, is an intensification and prolongation of the same unfavourable conditions. I am certain that cases in which local congestion is a prominent feature, and there are few in which it is not, are aggravated while on board; and I have never seen such reactionary beneficial effect following a voyage, as might be hoped for, or would justify the experiment of sending these cases to sea. Uterine displacements are especially liable to give trouble. Dr. Finucane, of the steamer *Servia*, tells me of a lady who had worn a pessary with comfort for over four years, except during two transatlantic passages, with an interval of nearly a year between, on each of which occasions it became necessary to remove the instrument. My own experience affords two instances, in one of which—a long-standing retroversion—the accustomed support could not be tolerated for nearly three weeks after landing. No doubt there may occasionally exist conditions of chronic disease associated with uterine inertia, in which a nervous and circulatory stimulus of this character would prove of immediate benefit. I will briefly mention a case in which some part of the satisfactory result seemed due to this influence. At Calcutta, during the winter of 1880 the wife of a surgeon in H.M. Indian Army was placed under my care for the return voyage to England. Her general condition was lamentable, and represented the worst effects of the enervating climate and surroundings. She had several miscarriages, suffered from profuse and irregular menstruations, and during the intervals from copious leucorrhœa. The os was patulous, and the uterus measured three inches and three-fourths. I determined upon the treatment recommended by Dr. Athill, (24) which has on several occasions proved satisfactory in my hands. I still further dilated the cervix, and through an extemporised canula swabbed out the entire uterine cavity with fuming nitric acid. The result far exceeded my highest expectations; and within one month following this procedure I had the gratification of handing over this lady in relatively perfect health. The treatment of uterine troubles during the ocean transit should be conducted upon general principles, and needs no special consideration. Ergot and opium control menorrhagia, but unless the loss was excessive, I have not thought it wise to check an irregular return of the menstrual flow. Morphia and atropia, duboisia, cannabis indica, and camphor, all prove useful in dysmenorrhœa, more especially when they can be administered by the hypodermatic

method, which is of inestimable value in all departments of maritime practice. No part of our subject is of more practical importance than that which still remains, and to which we can now afford but brief consideration—an estimate of the influence of sea-voyaging upon the course of utero-gestation.

During my service at sea, I became aware of 104 pregnancies, of which no fewer than 14 were terminated on board. Nine were at about full term, and of these it is probable that in at least two or three instances the voyage had been purposely timed, so that delivery might take place on ship-board, thus saving trouble and expense at home. Three were premature at about the seventh or eighth month, and two were abortions before the fourth.

In June, 1881, I had the peculiar experience of attending at three births during the first sixteen hours of the voyage, while still between Liverpool and Queenstown. All the labours were easy and rapid. The mothers and infants did well, and were landed in good condition. Of the miscarriages, one is worthy of special mention. It occurred at about the third month in a lady whose general health was excellent, who had borne three children to full term, had before crossed the ocean when six months pregnant, and had never previously aborted. If the uterine congestions produced by menstrual periodicity may justly be admitted as a cause of abortion (25) it seems certain that when the period occurs during a voyage this influence will be considerably intensified. At the same time, I am of opinion that, however active even upon the impregnated uterus, may be the ganglionic and sympathetic influences of motion, sea-sickness, and the mechanical disturbance of the viscera by violent and prolonged vomiting, is the main cause of premature labour and miscarriage at sea. In every delivery which occurred under my notice, with the exception of a single case in which labour had set in almost as soon as the ship weighed anchor—in all the premature cases, and all the miscarriages—the women were severely sea-sick before the commencement of uterine action. I am aware that this view is open to the criticism that the vomiting of kinetia should not be provocative of premature labour, since the ordinary vomiting of pregnancy, even when persistent and pernicious, has seldom a marked effect in terminating that condition. The possible utility of sea-sickness in certain conditions of pregnancy might even be considered by those who follow in the belief of Dewees, Bedford, and others (26) that the so-called physiological vomiting may prove beneficial in warding off abortion, and some of the other more serious neuroses incidental to the state. It should be remembered, however, that the vomiting of severe kinetia is more violent and unremitting than the morning sickness of pregnancy; that it has no claim to the term *physiological* as being a response to some abnormal reflex irritation, directly associated with that condition; and that it is most likely to excite uterine contraction at about the seventh or eighth month, a period of pregnancy at which the other vomiting is seldom troublesome. I have noticed that about this time violent kinetia almost invariably gives rise to spurious labour pains, which if not early checked will usually go on to the expulsion of the uterine contents. It is also extremely hazardous during the early months, and although the middle period is not entirely exempt from danger, when a voyage must be taken, it should, when possible, be arranged for the two months intervening between the conclusion of the fourth to the beginning of the seventh. Sea-sickness invariably perverts or entirely suspends lactation.

In recording these views and the grave caution which they imply, I am bound to state that other opinions, entitled to the highest respect, differ widely from my own. Dr. Forlyce Barker, at the date of his essay (1868), had never known a case of abortion from sea-sickness, and implies that such a result is extremely rare. Dr. Fourness-Brice, of the *Germanic*, has observed no very marked effect of the ocean transit upon

the course of pregnancy; he believes, however, that many are delivered soon after reaching land, and that if the Atlantic passage was twice as long the midwifery and mortality would both be immensely increased. In which opinions Drs. de Vere Hill, of the *Aurania*, and Finucane, of the *Servia*, generally concur. On the other hand, Dr. O'Loughlin, of the *Britannic*, with an experience of nearly fifteen years, and Dr. Leet, of the *Baltic*, hold views almost identical with my own. They have seen many premature deliveries and abortions, and consider sea-sickness the principal exciting cause. Dr. Exham, of the *City of Berlin*, in over four years' service has seen but one labour and one miscarriage. He has observed, however, the frequency of flying labor pains, commencing in the back and threatening parturition, and he attributes the satisfactory results in his practice to the care with which he has sought out and watched such cases, and to the free use of opium.

Among French writers on sea-sickness who allude to this matter, there exists more unanimity; but even from them we get nothing better than an occasional abstract opinion, based upon no stated observation or statistical deduction. With the exception of M. Obet, (27) who served four years in the *Compagnie Générale Transatlantique*, they are all agreed that a voyage seriously imperils the course of utero-gestation; (28) and this, I believe, fairly expresses the consensus of our present knowledge. No one will pretend that every pregnant woman who becomes sea-sick will abort during the voyage; and to cite particular instances of those who suffered severely from that distressing malady without disturbance of the uterine contents, is no more than could be done to prove the impotence of almost every well-known abortifacient. That so many competent observers agree as to this hazardous tendency, proves its existence; that others equally competent have not experienced similar results, only shows that this disturbance is not universally potent in overcoming the ever conservative energy of a natural and necessary process. Upon a secondary point we can scarcely expect more unanimity: Dr. Barker (29) has known several women who were always sea-sick when non-pregnant, and who were entirely exempt during pregnancy; Le Roy de Méricourt (30) has seen women sea-sick when pregnant who had not suffered before. My own opinion is most emphatically that pregnancy, more especially during the later months, predisposes to, and always aggravates, the most distressing features of kinetia.

As expressed by Spencer (31) "not directly, but by successive approximations, do mankind reach correct conclusions." If this paper stimulates those of greater ability and wider opportunity to pursue the line of study, here initiated, to more positive and scientific conclusions the highest aspiration of its author will be amply realised.

THE autumn course of holiday study in Berlin for 1885 for medical practitioners will commence on September 25th, and will last till the end of October.

## Lectures

ON

### HERNIA AND ITS RADICAL CURE.

*Delivered at the Royal College of Surgeons of England.*

By JOHN WOOD, F.R.S., F.R.C.S.,

Hunterian Professor of Surgery and Pathology;  
Senior Surgeon to King's College Hospital and Professor of Clinical  
Surgery in King's College.

#### LECTURE III.

IN the hollow of the groin below the inner extremity of Poupart's ligament, and forming, with the deep and superficial abdominal rings, an inverted triangle, of which it is the apex, lies the saphenous opening. Formed by the separation of the fascia lata into two layers, of which the outer or iliac part is advanced forwards by its attachment along the whole length of Poupart's ligament, and the inner or pubic portion covering the sloping surface of the adductor and pectineus muscles, is attached to the pectineal line, and continued behind the sheath of the femoral vessels to be continuous with the ilio-psoas fascia, and connected with the capsule of the hip-joint, the saphenous opening presents an oval outline, looking forwards and a little downwards and inwards. The outer border curves sharply inwards in a falciform manner, lies in front of the femoral vessels, and is attached to and blended with Gimbernat's ligament by a process about half an inch wide, Hey's ligament, important to surgeons, because it crosses the upper part of the crural canal, and may be the seat of strangulation. Below, the falciform edge passes under the saphena vein, receiving, as it does so, the veins which accompany the superficial branches of the common femoral artery, namely, the two external pubic, the epigastric, and the circumflex iliac. The two first pass inwards, the next upwards, and the last outwards. They supply the numerous lymphatic glands which lie in two groups in this situation, the upper directed obliquely along Poupart's ligament above and invested by Scarpa's fascia, and the lower lying parallel and internal to the saphena vein. Nearly all the afferent ducts of these glands pass in a body through the saphenous opening, the inner part of the femoral sheath, and the crural ring, to join the deep iliac and lumbar glands. The saphenous opening is covered in by a layer of fascia connected with its borders, called, from the numerous holes which transmit these lymphatics and some of the vessels, the cribriform fascia. This is blended, superficially with the deep layer of superficial fascia of the thigh, and, deeply, with the inner part of the sheath of the femoral vessels.

By detaching Hey's ligament from Poupart's, and turning down the fascia lata and cribriform fascia, the sheath of the femoral vessels is brought to view. It is arranged in three compartments; the outer for the common femoral artery, the middle one for the vein, and the inner one, smaller and funnel-shaped, is filled up by the afferent lymphatic ducts. On clearing these, it is found that they are held in position by a thin horizontal layer of perforated fascia containing a lymphatic gland, derived from, and continuous with, the subperitoneal fascia and fat of the iliac fossa, attached externally to the strong longitudinal septum, covering and protecting the femoral vein, and, internally, to Gimbernat's ligaments. This is the septum crurale of Cloquet, and is of little or no surgical importance.

If the finger be pushed upward into the iliac fossa, it will pass through the crural ring. Arching over it, in front, will be felt a curved border, formed by the union of the fascia transversalis with the deep fibres of Poupart's ligament, the deep crural arch. This is the usual seat of strangulation in crural hernia. Outside is the femoral vein, covered by its septum; inside, the edge of Gimbernat's ligament, to which the deep crural arch

is attached; and behind is the hinder part of the crural sheath, resting upon the pectineal line of the pubis, and the pectineus muscle arising from it, and covered by the strong pubic portion of fascia lata. Above and externally the epigastric artery arises from the external iliac trunk. Sometimes this gives origin to an irregular obturator artery, which may then descend into the pelvis close behind the border of Gimbernat's ligament.

Sometimes this branch arises from the external iliac itself, and then it passes down external to the crural ring altogether, and the precautions taken to avoid injuring the iliac vessels will also avoid the irregular branch. It is but rarely, however, that this vessel is cut in relieving the strangulation of a crural hernia. It yields readily to pressure in the loose subperitoneal investment. If the hernia-knife be not too sharp, it will cut the tense fibres of Gimbernat's ligament without injuring the loose yielding and elastic artery. In dividing the strangulating portion of the crural ring, the knife is usually directed inwards.

On opening the peritoneum and dissecting the crural ring from the abdominal cavity, it will be seen that a depression is formed opposite to that opening, internal to the iliac vessels. When the pubis presents a salient border or projection at the pectineal line, as in old age, it becomes more easy for the bowel, by its pressure, to obtain a purchase or hold for the formation of a hernial sac. It will also be seen that the peritoneum around is more closely attached to the subjacent structures than in the inguinal region. Hence the sac of a crural hernia is rarely so large as that of an inguinal one. The aspect of the crural ring is more horizontally placed than the deep inguinal ring. It faces upwards and downwards, with a slightly forward direction. The best guide to it is the pubic spinous process; which is about half an inch internal to, and a little above it; while Poupart's ligament is directly above.

The most frequent seat of strangulation is at the deep crural arch, or in the neck of the sac, at that point thickened by the continued pressure. Next frequently, the strangulating point may be the edge of Hey's femoral ligament, when the sac and bowel are bent outwards at an acute angle. Ill-directed attempts at taxis may here do much harm, and may even cause ulceration of the bowel at the point of constriction. This is especially apt to occur in elderly females, whose tissues are thinned and delicate, and the edge of the fasciæ and pectineal line sharp.

In a large crural hernia, the manipulation of the taxis should be at first directed inwards and downwards, and then backward, with a slight upward inclination of the neck of the sac. It is rare that directly upward pressure is required.

*Formation of a Crural Hernia.*—First, the sac is pressed downwards and slightly forwards, dilating the canal, along the lymphatic compartment of the femoral sheath, pushing before it the septum crurale, and spreading out the lymphatic ducts. It is then directed forwards, pushing before it the front wall of the innermost compartment of the femoral sheath and the cribriform fascia, and forming a tumour in the groin below Poupart's ligament and inside the femoral vessels. It then passes outwards and a little upwards, across the femoral vessels, where the fascial connections of the falciform process are weaker and looser than on the inner side, which is, moreover, supported to some extent by the numerous small vessels and lymphatic ducts before described. Finally, it lies with its fundus placed upon and above Poupart's ligament under the integuments, and its neck considerably in front of, and close to, the femoral vein.

In the course of the formation of a large hernia, Poupart's ligament is bulged forwards, and the groin loses more or less of the hollowness that it presents normally over the saphenous opening. The greater length and slenderness of Poupart's ligament in the female, with the greater width of the pelvis and of the hips, render them more liable to this form of rupture than the male sex;

while the latter, from the presence of the spermatic cord, are more liable to open abdominal rings and inguinal hernia.

The coverings of a crural hernia, are 1, the integuments, often thickened by the presence of a deep layer of fat, which may mask the position of Poupart's ligament, and render the diagnosis somewhat difficult. Enlargement of the femoral glands in these tissues may also tend to obscure the diagnosis, and mask the saphenous opening. 2, is the cribriform fascia, recognised by the perforations of the lymphatic ducts, often also obscured by fat and glands? 3, the fascia propria or crural sheath recognised by its superior density and fascial appearance. 4. *Septum crurale*, subperitoneal fascia, covering the sac, recognised by its greyish blue, sometimes greenish colour. 5th. The sac itself is often thickened, wholly or in part, sometimes presenting an hour-glass shape, from the crossing of vessels, regular or irregular. In one case, the shape was due to an irregular origin of the deep epigastric by a common trunk with the obturator from the common femoral, the former crossing and deeply indenting in front a crural hernial sac, and thus forming a very dangerous irregularity. The crural hernial sac and its contents are more liable to adhesions and abnormal positions of the omentum and bowel than in an inguinal hernia.

Thickening of the sac at the neck and adhesive blendings of the covering structures and glands may render it difficult to discriminate the tissues during operation. Or a varicose condition of the saphena or femoral vein may give rise to great difficulty and need careful precautions. By drawing down the sac and exposing Poupart's ligament and the pubic spine clearly, a good guide is obtained in difficult cases. In large and old standing cases, very often no discrimination between the different layers of covering is possible. In operating, the femoral vein should be carefully protected by the finger or a small spatula, and both Poupart's ligament and the pectineal fascia should be kept distinctly in view, as well as the edge of Gimbernat's ligament.

*Operation for the Radical Cure of Crural Hernia.*—The skin of the groin being shaved and washed with carbolic lotion, and the patient anaesthetised, a fold of skin over the site of the hernial tumour should be pinched up, and scalpel or tenotomy-knife, carried with its edge upwards, cutting towards the surface in a vertical line. This will usually expose the cribriform fascia. In a stout subject it is better to dissect down, through the fat, in successive layers. The deeper tissues are then cut through, down to the sac, which is to be opened by pinching up a portion, lateralisation of the knife, and with or without a director, slit up vertically. With the handle of the knife the sac is then carefully separated from the surrounding structures, then it is opened, the contents examined, and thickened, elongated or adherent omentum removed, after ligature of the vessels separately with thin catgut. The sac being carefully emptied, is to be transfixed at the neck with the handled hernia-needle, carrying a stout tendon ligature, tied on each side, and cut off close.

Next, the needle is carried through the deep layer of the crural sheath, and pubic portion of fascia lata, entering an inch below the crural ring, and emerging close up to the pectineal line, at the side of the femoral vein, which is to be carefully protected by the finger or a spatula. The needle is then carried through Poupart's ligament, emerging at the upper part of the incision. It is then threaded with one end of the same stout piece of tendon, used to ligature the sac, which is then drawn down, emerging at the lower part of the incision. The needle is then again to be passed at the inner side of the wound, through the pubic fascia lata skirting Gimbernat's ligament, and transfixing a second time the inner end of Poupart's ligament. The upper end of the tendon ligature is then attached to the eye of the needle, and brought down, the two ends tied with a double surgeon's knot, or, if wire be used, twisted by two turns. The effect will

be to draw, backwards and downwards to the pubis, the inner end of Poupart's ligament, and to close up the crural ring completely. A piece of small drainage-tube, or horsehair, is then placed along the wound, from the ring to the lowest angle; the wound closed by closely-applied interrupted sutures, and gauze or cotton wool dressing applied in the usual manner. Latterly, I have found the use of tendon ligature so satisfactory, that, for this operation, I prefer it to wire. The wound usually closes over it and heals by adhesion at once, and there is not the pain and inconvenience of the withdrawal of the wire. So far the endurance of the tendon, when buried in the tissues, has been long and satisfactory enough to maintain the cure, in some cases for above two years.

*Operations for the Radical Cure of Hernia after Kelotomy for the Relief of Strangulation.*—At the meeting of the British Medical Association at King's College, London, in August, 1873, in the address given by me to the Surgical Section, I described an operation, performed in March of the same year, for the closure of the inguinal canal and rings, after relief of the strangulation by kelotomy. The hernia was a large one, the bowel strangulated to a chocolate colour, and the sac contained inflammatory serous effusion. The case did excellently well, no peritonitis ensued, and the patient was shown to the members of the Association wearing no truss. The steps required, in addition to the ordinary operation of kelotomy with opening of the sac, consisted in ligature of the neck, and the application of wire for the closure of the canal and rings, in the same way as in the subcutaneous method. In all, I have ligatured the neck of the sac flush with the peritoneal opening, and in some removed it altogether, and then laced up the canal and rings, with wire or tendon-ligature.

I have operated for the radical cure of strangulated hernia, after kelotomy, in sixteen cases—namely, eight inguinal and eight crural. Seven were done by ligature of the neck by catgut and entire removal of the sac, with the closure of the canal and rings by wire-lacing, and nine by the use of tendon for all these purposes. Of these, one case of inguinal in a male, and one of crural in a female, died from the effects of the strangulation upon the bowel. In neither did the removal of the sac or the closure of the canal appear to add to the risk of a fatal result, inasmuch as none of the *post-mortem* morbid appearances implicated the rings or the canal, but were confined to the bowel, omentum, and visceral layer of peritoneum. Such, indeed, is usually the case in the cases of death from the operation for the cure of hernia. It is rare to find any amount of peritonitis, and still more rare to find morbid appearances affecting the sac or canal.

The history of hernia shows that the sac may be twisted, perforated through and through, injected with irritants, ligatured or removed altogether, or may slough off without any appreciable amount of peritonitis; and that death, when it ensues, is far more often from blood-poisoning, erysipelas, and such diseases as may occur from any operation, than from peritonitis. We may, therefore, conclude that, antiseptic means being employed to prevent such results, the attempt should be made to cure the patient of the hernia after kelotomy, in all cases where the condition of the bowel renders it safe to return it into the peritoneal cavity, after the relief of the strangulation. The omentum may be dealt with more freely than has heretofore been done. If sphacelated or suspicious in appearance, the vessels may be taken up in a healthy part above, tied with small catgut, and the doubtful part removed by tearing, or with a pair of blunt scissors. This may be done by spreading out the omentum, and taking up the vessels, which are usually plainly seen from the congestion of the veins, with a piece of thin catgut, applied by a common suture-needle, aneurism-needle, or a common pair of dissecting-forceps.

In a very few cases, indeed, a cure of the hernia may occur after kelotomy, where no attempts have been made to close the sac or canal; but, ordinarily, the division of

the strangulating structures leaves the hernial aperture much more patulous, and the hernia larger and more uncontrollable by trusses than before. To prevent this by an addition to the ordinary operation of kelotomy, which does not appreciably increase the risk, and is effected while the parts are exposed by that operation, seems to be a course of proceeding which will commend itself to most surgeons.

*Umbilical Hernia.*—The anatomy of the umbilicus is sufficiently simple. An opening left in the *linea alba* at the side of the exit of the omphalo-mesenteric duct between that and the closed urachus from imperfect development sometimes permits at the period of birth a portion of bowel to protrude into the substance of the umbilical cord during the pressure and struggles of parturition.

On examining the infant before the application of the ligature to the navel string, the appearance of the latter should be carefully noticed when the infant cries. If any swelling takes place, or the cord appears thicker than normal, the sac, which is composed of the tissues of the funis, lined by a thin layer of serous membrane, should be carefully compressed, so as to exclude the bowel, if present, and a broad ligature placed nearly flush with the surface of the integuments. By this means the rupture may be at once cured.

To tie the cord at a distance from the navel is in these cases to invite the occurrence of an umbilical hernia, while no harm can result from the application of a thick silk ligature in the way just described if the swelling be carefully manipulated to exclude any bowel which may be present in the sac. Often the weakness at the navel opening is unobserved, or the treatment by a pad and belt is discontinued too soon, and the result is the appearance of an infantile umbilical hernia, when the muscular system of the child becomes more powerful and the efforts in crying more continuous. Sometimes, although no hernia may at once ensue, a weakness is left in the site of the aperture, and a piece of omentum may pass in and out of the sac, preventing the circular contraction of the tendinous cicatrix, which should seal up the opening and cure the hernia. The original weakness may persist, and the first occurrence of the hernia, though this is not commonly the case, may happen in adult life or even in its decline. At this time the accumulation of intra-abdominal fat, the occurrence of pregnancy or ascites, or the habitual distention of the bowels by air, may produce a rupture here. In such cases the navel cicatrix never presents the cup-shaped depression of a strong and healthy development. The peritoneum covering the inner surface of this point when healthily developed, is tough, grayish-white, and presents small puckerings, produced by the contraction of the cicatrix, which binds the margins of the umbilical aperture together.

In hernial cases this part is looser, more bulgy, and less firmly adherent. As the hernia gets larger by the intrusion of omentum, the peritoneum becomes stretched, and finally is much attenuated as to be incapable of demonstration, so that we may look in vain in a long established case for a real peritoneal sac. The sac is a blending of the stretched and attenuated cicatrix with the remains of the peritoneal structure.

The abdominal wall gives way, in fact, at its weakest part, under the distention. In such cases that part lies in the navel, and not in the groins. In some instances the small apertures in the middle line aponeurosis, which usually transmit the small intercostal vessels and nerves, may become dilated by the growth of pellets of fat, which gradually enlarge them, and finally may permit (when the patient from any cause, becomes afterwards thin), the occurrence of a rupture close to the navel, and apparently (at first sight) umbilical. It will be found, on close examination of such cases that the aperture is on one side of the real navel. The umbilical hernia of adults is always formed in one of the ways just described, but most frequently in the way

first mentioned, and usually there is a history of infantile or congenital weakness in the part. From the exposed and prominent position of the rupture the part is liable to the results of pressure and friction, or injury. The sac may be rendered irregular in shape, bulging out on all sides, like a mushroom, and thickened irregularly by hypertrophy. The omentum within is very liable to become adherent, or thickened in lumps of fibrinous effusion. Or the bowel may be adherent to the omentum or sac.

Such changes are more commonly found at the lower part of the sac. This is brought about by the weight and pressure of the contents downwards upon the sharp lower curved edge of the hernial opening; while the pressure of the clothing, or even of a belt or truss worn to support the rupture; but often ill-fitting, pressing downwards instead of lifting upward, and uncomfortable to the patient, as well as injurious, produces a constant irritation and shifting of the pressure.

Hence it is found that the strangulating part of an umbilical hernia is placed at the lower edge, with the bowel hanging over it, and sometimes sharply ulcerated through, with extravasation of fecal matter into the sac. Not uncommonly, however, the strangulating part is intrasaccular, produced by the adhesions or omental openings, and may be, during operation, difficult to find and to separate from the matted tissues.

The transverse colon is usually involved in an umbilical hernia, but by no means invariably so. Frequently the small intestines are found in the sac, generally the omentum; in a few instances, a portion of the stomach and spleen.

In applying the taxis or any supporting apparatus to a large umbilical hernia, the pendulous position of the fundus must be carefully borne in mind. The pressure should be a lifting pressure towards the umbilical cicatrix. If this is not attended to, the bruised and damaged bowel is pressed and rubbed upon the cutting lower edge of the hernial aperture, and still further damaged, or even ruptured. The fundus should be placed in the hollow of the hand, and lifted up gently, while the fingers of the other hand manipulate the neck of the sac by the gentle kneading motion.

*(To be concluded in our next.)*

## Clinical Records.

### INTERMITTENT ALBUMINURIA WITHOUT APPARENT DISTURBANCE OF HEALTH.

Under the care of Dr. MEKLEN, Paris.

THE patient, a youth sixteen years of age, had usually enjoyed good health, but, being the son of gouty parents he himself presented the characters of the lymphatic temperament, extremities cold and blue, pale complexion, the limbs of exaggerated growth as compared with the trunk, and delicate skin, with a tendency to acne. Towards the end of last September he was seized on two successive occasions, after taking horse exercise, with sudden and fleeting loss of vision. This occurrence led to consultation of a medical man, by whom it was suggested that the urine should be examined, the result being that this excretion was found to contain a considerable quantity of albumen. This was the more surprising because the other organs were free from disease, and the general health good, so that it was impossible to entertain the idea that nephritis existed. Provisionally the patient was confined to his chamber, and put on a milk diet.

Careful and continuous examination of the urine for a week showed that a considerable quantity of albumen existed in it from midday to midnight, but not a trace during the intervening hours. This phenomenon, joined to the absence of any other suggestive symptom, excluded the supposition of a renal lesion, which was, moreover, rendered

improbable by the non-existence of any casts, although the urine was several times examined for them. As a complement to this negative diagnosis the eyes were examined by the ophthalmoscope, the acuteness of vision was perfect, but the eye a little hypermetropic. Retinae healthy, no traces of the lesions usual in albuminuria; the only anatomical peculiarity being a certain hardness (possibly congenital) of the optic nerve fibres, and at one point a delicate injection of the same nerve. The retinal veins were relatively slightly turgid, this being assigned to some atonic condition of the vaso-motors. The temporary impairment of vision was regarded as due to sudden suspension of accommodation in a hypermetropic eye, which was as suddenly rectified.

Two examinations of the urine passed at intervals of several days gave the following results:—(1) Urea, 15 grammes, in 24 hours; uric acid, '59 grammes. Albumen in considerable amount, but not found at night. The microscope reveals a very few leucocytes, and some epithelial cells. No sugar. (2) Urine passed between midday and 6 p.m. This contained eighteen centigrammes of coagulated albumen per litre.

The ophthalmoscopic examination having been productive of negative results only as far as regarded the retinal lesions usually found in albuminuric subjects, and the albuminuria itself intermittent and moderate in degree the patient was permitted to return to school, and the rigidly enforced diet relaxed, but he was ordered to drink milk rather than wine, and to avoid severe exercise and chills. Continuous examinations of the urine gave the same results as previously detailed. On February 14th, the patient was suddenly attacked with a violent fever, attended by pain in the side, and resulting in an acute chest affection having the characters, first of diaphragmatic pleurisy, next of pleuro-pneumonia. This febrile attack persisted twenty days, with sweating and sudamina; the condition of the patient was grave at times, the evening temperature varying from 39 to 40° C. The strange fact in connection with this period, however, is, that throughout it the urine never contained a trace of albumen, although examined at frequent intervals, and at all times in the 24 hours. Subsequently, the fever abated and convalescence was established, but the albuminuria did not return, although a meat diet was regularly indulged in at this time. Nor on getting up did it return, and a hope was entertained that the fever had exercised a curative influence over it. As soon, however, as the patient commenced to move about as usual this expectation was dispelled, and the urine being one day examined about this time, soon after breakfast (*dejeuner*) the characteristic albuminous precipitate was once more observed. Next morning it had disappeared, and thenceforward the same phenomena which were witnessed anterior to the fever were reproduced, but with the difference that as time proceeded the amount and frequency of the albuminous deposit grew less, and some prospect of amendment was apparent, with attending improvement in the patient's general health.

ACADEMY OF MEDICINE IN IRELAND.  
SUB-SECTION OF STATE MEDICINE.  
THURSDAY, APRIL 16, 1885.

The President, Dr. J. W. MOORE, in the chair.

### ON THE RESULTS OF THE APPLICATION OF THE LAWS RELATING TO THE ADULTERATION OF FOOD AND DRUGS.

SIR CHAS. A. CAMERON stated that the first Act relating to adulteration of food and drugs had been passed in 1860, through the influence of Mr. Scholefield. Only three public analysts were appointed under the provisions—Dr. Letheby, by the Corporation of London; Dr. Bell, by that of Birmingham; and the author, by that of Dublin. With the exception of Dr. Bell, the author was now the senior public analyst in the United Kingdom. The Act of 1860 was not put into force in any town save Dublin. In 1862 a public analyst was appointed, and the following year the clerks of the markets collected articles for analysis, and several of them were found to be adulterated, and the vendors were successfully prosecuted. The defects in the Act were, how-

ever, conspicuous. No officers could be appointed under it whose sole duty it would be to act as food inspectors. The fines levied for breaches of the Act were payable into the Imperial Treasury instead of into that of the local authority charged with the execution of the Act. The seller of the inspected articles had the option of accompanying the purchaser to the analyst—obviously a privilege which, in the case of country districts, prevented the Act from being worked. Notwithstanding its many defects, this Act was worked in Dublin for ten years, and was the means of putting an end to the practice of adulterating many of the articles of food in common use. A very large number of convictions for the sale of adulterated articles were obtained in Dublin. In 1872 another Act was passed which enabled local authorities to appoint food inspectors to collect articles for analysis. A defect in the first Act was remedied—namely, appointing the Courts of Quarter Sessions instead of Grand Juries in Ireland to be the appointing authorities. In England the Courts of Quarter Sessions are fiscal bodies and the Grand Juries are not, while in Ireland the Grand Juries are fiscal bodies. By the Act of 1860 the Irish Courts of Quarter Sessions could appoint but could not pay public analysts. Only one court made an appointment—namely, that of the County of Dublin. In 1875 a third Act was passed. It repealed the section enabling the vendor to accompany the purchaser to the analyst. This alteration enabled the Grand Juries of the County to appoint analysts in cities outside of the counties. In Dublin these Acts have, on the whole, worked fairly. At first it was found that bread, flour, tea, coffee, mustard, sweetmeats, and milk were largely adulterated. Now, with the exception of milk, it would be difficult to find an adulterated article in Dublin.

The PRESIDENT inquired whether Sir Chas. Cameron had met with many cases of adulterated butter, instancing butterine and bosh butter.

Sir CHAS. CAMERON said there was a great deal of bosh butter sold; but within the last few years a new form of adulteration had been introduced by incorporating water in the butter. Quite recently, in Drogheda and Newry, there were cases in which 45 per cent. of water had been incorporated.

Dr. WRIGHT, speaking from personal knowledge, said there were a great many instances of adulterated drugs having been supplied to dispensaries.

Sir CHAS. CAMERON said he too had met with many cases of adulterated drugs.

Dr. STRAHAN, adverting to the adulteration of milk in the city, mentioned a case in which a lady who resided at Drumcondra about twelve months ago, having found fault with the milk she was getting, made a change, but no sooner had she partaken of the fresh milk than her stomach became sick, and she had a miscarriage in twenty-four hours.

Dr. J. KNOX DENHAM considered that many of the stomach disorders among children were due to eating adulterated sweets, especially sugar-stick which was hawked about by rag gatherers. He instanced a case in which a woman, convicted for selling butterine for butter without notice, recovered £100 damages from the merchant who sold her the butterine as butter.

Dr. MACDOWEL COSGRAVE stated that, when in Huddersfield, he found that a great many traders were convicted for adding salt to the beer—a practice that was adopted at the dinner hour, when the mill hands were set free. He asked whether that practice existed in Dublin, and whether whisky was adulterated?

Dr. HENRY KENNEDY said he had frequently seen children whose illness he could attribute to nothing but adulterated sweets. He believed plaster of Paris entered largely into their composition, especially of almond sweets, and that the colouring matter was also deleterious. The only pure sweet, in his opinion, was sugar barley. However, as he had seen the certificate of pure sweets, he asked whether there were any sweets really pure, in the proper sense of the term. As to milk, he had seen white powder in it, and the specific gravity being made up in a way that he could not explain, and he had heard that calves' brains were mixed with milk. What the adulterants other than water were he was anxious to know, both with regard to milk and butter.

The PRESIDENT considered that vermilion was more likely to cause obstinate diarrhoea than any other symptom of mercurialisation, and that possibly the great fatality of diarrhoea in Dublin was to a certain extent, due to the enor-

mous indulgence by children in sweets. Of sweets, one of the safest was the crystalline sugar-candy, the crystals being unlikely to take up obnoxious or adulterant matter.

Dr. MONTGOMERY inquired the cause of the deterioration in the quality of butter. Whether from adulteration or the mode of feeding milch cows, it was exceedingly difficult to get eatable butter now compared with fifteen or twenty years ago.

Sir CHAS. CAMERON, in reply, said it was perfectly true that a great deal of adulteration was practised in drugs, and many were spurious, especially bark preparations. He met an instance of sulphate of cinchonine being sold as sulphate of quinine, and audaciously labelled "Howard's." In the United Kingdom an enormous adulteration was practised in butter. When a small quantity of butter was used to sophisticate pure butter, it was difficult to state positively the butter was not pure. The way in which the adulteration of butter by butterine was arrived at was a curious one. In all kinds of fats there were certain quantities of fatty acids, soluble in water. As the result of analysis, it was found that not more than 3 per cent. of the fatty acids in suet and lard dissolved in water, whereas 7 or 8 per cent. of butter fats dissolved. Therefore, when he got less than 3 per cent. there must be the common fats present not butter fats; and similarly, when he got 6 or 7 per cent. there was pure butter. Butter fats were peculiarly constituted, being physiologically intended to be eaten raw, whereas the others were intended to be eaten cooked. As a popular test, in warm weather butterine was much firmer than pure butter. Butterine rolls cracked across, but butter was plastic, and hence the more brittle the roll the greater the amount of butterine fats. He believed there was a great deal of butterine adulteration, and as public analyst he was most anxious to put a stop to it. But Dr. Montgomery's complaint pointed to another defect, and that was, the complete carelessness in the manufacture of butter. From his early days he knew a good deal about experimental farming, which he studied at the Albert Model Farm, and he had written on the butter manufacture. Speaking from a knowledge of the subject, he stated advisedly there was no worse butter made in the world than in Ireland. There was a total disregard of cleanliness, and the salt used was extremely bad. In the west of Ireland he positively saw milk put under the bed to set for cream, that place being chosen to protect it from the fowl, and perhaps to increase the quantity, though not the quality. The only way to improve the butter was to establish butter factories, as in America and in Denmark. It was a common practice with the large farmers in Denmark to get milk from the smaller ones, and, having extracted the cream, return the skimmed milk for food purposes. But a different system prevailed in Ireland. There were a great many small farmers, and no proper dairies. Pedlars went round and collected small quantities of butter, which they mixed up together to make it homogeneous. Therefore the bad manufacture accounted for the bad quality of the Irish butter. The brains theory of adulterated milk had been long ago exploded, being impossible to carry out. There was little adulteration practised except with water. He found flour seldom, sugar occasionally, and salt frequently, and not long ago he found rice, flour, sugar, salt, skimmed milk, and fore milk, which was the milk first drawn from the cow, the strippings being kept to manufacture into butter. There was no adulteration of sweets at present in Dublin. He had analysed hundreds of specimens during the last four years without finding plaster of Paris, white clay, or poisonous pigments. The yellow was from saffron, and the pink from carmine. He found the yellow stuff sold in the street to be composed of a small quantity of honey, and sugar, and flour. Eating large quantities of sweets and diarrhoea resulting did not prove that the sweets had been adulterated. Pastry made children and adults ill. The only question was, whether the raw flour in the cheaper kinds of confectionery might not produce some bad effects. But the common sugar-stick was nothing more than sugar partly candied by being heated in an iron pot and rolled upon a flag. Comfits were perfectly pure at present. Several times he found salt in beer, but not so often here as in England. A low-class beer was manufactured from molasses. Having had the misfortune to certify that an article sold near Belfast was a debased, spurious production from molasses, deficient in solids, and containing little or none of the extract of barley, the vendor was fined £50—a conviction which was confirmed on appeal.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.  
MEETING HELD IN THE BRADFORD INFIRMARY, TUESDAY,  
MAY 5TH.

Dr. GOYDER, President, in the chair.

#### PATHOLOGICAL SPECIMENS.

MR. CARTER showed specimens taken from the intestines of two patients who both suffered from severe abdominal pain with vomiting, the first dying six weeks, and the second four weeks, after admission, yet whose pathological conditions were found to be quite different from one another. Both cases were those of young men, J. D. being *æt.* 20, and J. K. 17. In J. D.'s case the small intestine showed alternate dilatations and contractions along its whole course, but mainly affecting the ileum. Colon healthy. On opening the intestine the contractions of the gut were found to be due to masses of cicatricial tissue passing horizontally across the lumen of the bowel. So narrow was the contraction in one place that only a knitting needle was allowed to pass the opening. Mesenteric glands much enlarged. In Mr. Carter's opinion this was a case of tubercular ulceration of the intestine, the extension of the bands across the lumen of the bowel, and the great enlargement of the mesenteric glands confirming him in this view. (Under care of Dr. Alexander.)—Case 2, on the other hand, was one of lymphosarcoma of the small intestine. It was under the care of Dr. Goyder. In life a doughy swelling had been made out, the size of a medium-sized orange, in the hypogastric region. During an attack of pain the abdomen became irregularly distended, and the swelling hardened, as if there were some accumulation, or some constriction of the gut. *Per rectum* a hard movable mass could be felt just within reach of the finger, and apparently fixed to the promontory of the sacrum. On post-mortem examination the intestines were distended with flatus and fluid fæces, and a coil of small intestine was found firmly adherent to pelvic walls, and surrounded by an irregular mass of new growths, brain-like in consistence. The whole length of the small intestine was found to be more or less affected by new growths from the size of a bean to that of a walnut, and increasing in frequency and size towards the ileum, where they projected into the cavity of the bowel, but did not much diminish its calibre. On section the masses showed marked absence of stroma, with abundance of small nucleated cells.

Remarks on these interesting specimens were made by the President and Dr. Denby.

Dr. RABAGLIATI then read a note on

THE CONNECTION BETWEEN FEVER AND INFLAMMATION, as shown by the occurrence of a case of diphtheria which seemed to be caused by metritis in the puerperal state. Dr. Rabagliati commenced by offering these definitions of inflammation and fever respectively: "Inflammation is the result of the interaction between the organism and inorganic causes." "Fever is the result of the interaction between the organism and organic causes." By inorganic causes he meant cold, heat, damp, injury, &c. By organic causes he meant all forms of organic matter, whether so highly developed as to have reached the stage of spores or not. For the moment he took no account of the difference between the causation of specific inflammations, as they are called, and fevers proper, as it was not necessary to his argument to settle, *e.g.*, whether typhoid fever was a fever proper or a specific inflammation of Peyer's glands, with other like questions. Dr. Rabagliati said that for a long time he had been convinced that many of the ideas prevalent about fever are erroneous, and instanced that extraordinary and oft-repeated statement that "fevers run a definite course," contending that if one feature rather than another characterised such a fever as typhoid, it was not the definiteness, but the indefiniteness of its course. He also thought there was much evidence for the view that fevers run into one another. His case was this: A primipara was confined on 7th Feb., 1885. For a month before confinement she had not been well, though not sending for the doctor. She had, for instance, been so hot at nights that in the cold month of January she had never been able to bear more than a sheet to cover her in bed, and had drunk frequently at nights of cold water. During the day of the confinement the tongue was dry and furred. Labour lasted fourteen hours. She had chloroform

and two doses of ergot. No other interference. On February 9th, patient low, dull, and complaining of headache and backache. 10th and 11th, worse. T. 102.6. Ordered icebag to abdomen and one to head. On the 12th, in spite of icebags, temp. 102.2, but by more free use of ice it gradually fell, and on the 13th was 98 F. During the course of the illness there were repeated rigors, profuse sweatings, and on the 15th the whole body was covered with a lichenous rash. There were signs also of inflammation of left side of cervix and body of uterus. The inflammation crept from point to point, but never involved the whole uterus. Dr. Dobie, who saw the patient on the 14th, diagnosed simple creeping metritis. On the 12th and 13th there was a bad smell noticeable when one entered the room. On the 17th the monthly nurse, who had been most unremitting in her attentions to the patient, and who, no doubt, saved her life, showed a grey patch on the left tonsil. On the 18th she went home. On the 20th Dr. Hime saw her, and agreed with Dr. Rabagliati that the nurse had true diphtheria. She said she had sore-throat two days before she mentioned it, so that it would begin on the 15th. As the incubation of diphtheria is three or four days, it is certain she caught it in her patient's house. The house, it may be said, was examined and reported on by the Engineer of the Bradford Sanitary Association, and alterations in the sanitary arrangements made at his suggestion. At the same time the housemaid, who brought her mistress's meals upstairs, had a herpetic pustule on her nose, and the husband of the patient had a sore-throat, with a crimson colour, not diphtheritic. The cook, who did not go to her mistress's room, was not ill. Dr. Rabagliati thought the facts justified his view that the puerperal patient was in a low state of health before confinement, that she took a low form of metritis in consequence, that she infected the nurse with diphtheria, the housemaid with the pustule on the nose, and her husband with dark sore-throat, and that this was therefore a case which showed that inflammation could generate a fever (or specific inflammation) like diphtheria. If inflammation could breed fever, then he thought it likely fevers did not always breed true. In support of his argument he instanced epidemics of scarlatina, where in one house some persons take scarlatina and some a sore-throat without rash. He also said that in a houseful of children he had often known a child take a simple cold which induced in turn a specific cold or fever in a second child, the last being far more difficult to treat and running a longer course than the first. To put the case in terms of the definitions on which he had ventured, he thought that an inflammation, produced by inorganic causes, might generate a fever, produced by organic causes, and that this was a case in point.

A discussion followed, in which the President, Drs. Burnie and Denby, and Messrs. Mossop and Ellis took part, and Dr. Rabagliati replied.

Mr. R. H. MEADE then read some remarks on

#### THE PATHOLOGY OF PURPURA,

which, he said, had been a puzzle to him all his professional life, and he hoped now rather to receive information than to throw light on the subject. One reason for obscurity was that many difficult forms of disease had been confounded under the name purpura. Purpura, he said, is not a disease after all, but a symptom, and scurvy and purpura were often confounded, yet they were really distinct, and not amenable to the same form of treatment. Petechiæ, again, vibices, ecchymoses, &c., occur in such different states of system, some plethoric, others anæmic, that they cannot arise from the same causes in the blood. The ordinary division of purpura into simple and hæmorrhagic he thought artificial, and suggested a division into plethoric and anæmic, to which, perhaps, adynamic, or putrid (found in malignant small-pox and typhus), might be added. The characteristic sign of purpura was a spot or spots of red purple colour on the skin. Sometimes marks are seen as of bruises which go through the same changes of colour as the latter, and sometimes bullæ are seen filled with blood, or blood may be effused among the muscles, and supuration and sloughing may occur. Even the gums may bleed, as in scurvy, and there may be internal hæmorrhages. Mr. Meade then mentioned four cases of purpura he had seen, the first occurring when he was a medical student. It was a second attack, and occurred in a woman whose forearms showed cicatrices of the former attack. Bullæ, filled with blood, formed, and sloughing among the muscles followed. The

case slowly recovered. Case 2 occurred in a young married woman who was weak from over-suckling, and who was vomiting almost all the food she took. Blood also passed from the bowels, not florid as in piles. By and bye blood appeared in the urine, and in a few days more an exanthematous eruption, like roseola, came on on the limbs, and this was quickly succeeded by spots of the true purpura. The case was very troublesome, and characterised by numerous relapses, the irritability of stomach rendering it particularly difficult of treatment by food and medicine, but it ultimately recovered perfectly. Case 3 occurred in a middle-aged plethoric woman of drinking habits, whose face and limbs and great part of the body were covered with livid blotches, the upper eyelids being converted into bags of blood. The gums were spongy, and bled, as did also the palate and fauces. This case died. Case 4 was that of an oldish gentleman, a free liver, of full habit, who had purpura on the legs, which soon got well, but shortly after he died of an attack of apoplexy, and Mr. Meade asked if this was a co-incidence, or another phase of the disease. *Causes.*—The causes of purpura are various. In scurvy it is due to the absence of salts of potash. In hæmorrhagic small-pox there is a putrescent state of blood. In other cases the causes are obscure. Iodide of potassium and chloral have been known to cause it, and it has been found both in anæmia and plethora. The pathology is interesting, but obscure. What causes the capillaries to give way? Dr. Wilson Fox, found degeneration of the minute vessels in some cases, but could this come on suddenly? How does the serum exude in pemphigus? In cases of fracture we often find large bullæ filled with blood in parts of the skin not apparently bruised, and also in cases of incipient gangrene. Can the nervous system be at fault, as in cases of herpes zoster? The treatment must vary according to the nature of the cause, so far as it is known, and may be in some cases administration of fresh vegetables; in others, purgation, or bleeding; and in others, tincture of steel, turpentine, or ergot, &c.

In the discussion which followed, the President, Drs. Burnie and Rabagliati, and other gentlemen took part.

#### BRIEF NOTES FROM OUR EXCHANGES.

THE SPINAL ARTHROPATHIES—A CLINICAL REPORT OF SIX CASES OF CHARCOT'S JOINTS.—Dr. A. Sidney Roberts contributes a very interesting paper upon his clinical experience of this class of cases, in the *Philadelphia Medical Times*, April 18th, 1885, p. 523, to which, those interested in the subject will do well to refer. In all, the development of the "ataxic" nerve symptoms preceded *pari passu* with the development of the joint changes, but in some there was slight precedence of the one or the other. The following are the practical deductions Dr. Roberts draws from the clinical study of his cases:—"Period of Development.—1st. The tabetic arthropathies may occur independently, or precede the active symptoms of locomotor ataxia. 2nd. They occasionally develop suddenly late in the course of a posterior spinal sclerosis. *Nature of the Lesion.*—The peripheral expression of central nerve irritation is characterised by the following changes found in the structure of the various articulations. 1st. A chronic asthenic hyperæmia of the synovial membranes, a hydrarthrosis. 2nd. An interstitial atrophy of the epiphyses. 3rd. A fungous or rarefying epiphysal hypertrophy. 4th. The formation of osteophytis and bony stalactites. These various joint-expressions characteristic of the spinal arthropathies may exist separately, but are usually combined in the same subject. *Differential Diagnosis.*—They may be readily distinguished from the common inflammatory lesions of the epiphyses by the total absence of the reflex neural phenomena, i.e., of pain, both reflex and local, the apprehensive state regarding joint movements, and the reflex or tetanic spasm of the muscles always associated with joint arthritis. Abscess is never directly associated with the arthropathies, unless incident upon direct traumatism. They are more difficult to differentiate from malignant disease of the articulations, but a careful inquiry into the history and course of the lesion, and the presence or absence of central disturbance, are our most reliable guides. *Course.*—This progress of the arthropathies is essentially chronic. Occurring early, not unfrequently in the history of the tabetic

lesion they slowly increase, with occasional exacerbation, and years elapse before fully matured. A rapidly developing arthropathy may be associated with the later stages of an ataxia. Their course is self-limiting, though never reparative.

**TREATMENT OF PSORIASIS.**—Professor Fournier's formula for the treatment of this disease is as follows:—  
R Chloroform, 8 parts; Gutta-percha, 1; Crysophanic acid, 1; M. To be applied with a brush to part affected. It has the special advantage of forming a pellicle by means of which the medicine is kept applied to the part.

**AN ORIGINAL OPERATION FOR RUPTURED PERINEUM.**—At a recent meeting of the New York Academy of Medicine, Dr. A. C. Past read a brief paper on this subject. He had successfully performed the operation he proposes upon three cases. The following are the advantages he claims for it:—  
1st. Simplicity in execution. 2nd. The securing of a more solid perineal body. 3rd. No loss of substance in its performance. 4th. Repetition easy should the first operation fail. The method of operating is as follows:—"An incision was made on each side of the vagina to the depth of fifteen or twenty millimetres. The incisions meet in front in a manner to divide the parts into an upper and a lower segment. The upper segments were turned up and formed the floor of the vagina, and were secured in position by a row of catgut sutures passed, not through the skin, but through the subcutaneous cellular tissue, so as to turn the edges of the skin upward to form a ridge on the floor of the vagina. A second row of sutures, of silver wire, were passed from either side through the deepest part of the incisions, where the upper and the lower segments met. The ends of these sutures were passed through glass beads and perforated shot, and after the flaps were brought into close contact the slits were compressed. The inferior edges were united by fine sutures, and an iodoform dressing was then applied. The integument on the inner side of the thighs should be protected from pressure by the shot and beads. The patient should be allowed to urinate without the use of the catheter, and the parts be washed afterwards with a solution of mercuric bichloride. The sutures might be removed at the end of ten days or a fortnight.

**ERGOT IN ACNE.**—Prof. Broca (*Therapeutic Gazette*) finds ergot in doses of 15 to 30 grains daily, and washing morning and evening with warm water containing a little spirits of camphor, or even eau-de-Cologne, are often more effectual in relieving the unsightly simple acne than harsher measures.

**HOT BATH IN PUERPERAL ECLAMPSIA.**—Dr. C. Breus, in the *Journal de Médecine*, asserts that he has obtained very favourable results by immersing the patient in a bath of 100°, and then raising the temperature of the water as high as can be tolerated. After half-an-hour, the patient is placed in bed and wrapped in warm blankets for three hours. The immediate effects are profuse diaphoresis and sleep.

**OIL OF EUCALYPTUS IN BRONCHITIS.**—Prof. H. C. Wood reports, in the *Therapeutic Gazette*, that in his hands the oil of eucalyptus in ten minim doses (in two gelatine capsules) four times a day, has replaced all stimulant expectorants in chronic or obstinate sub-acute bronchitis.

**NITRATE OF SILVER IN OPHTHALMIC NEONATORUM.**—“Prof. Credé, of Leipzig, has successfully prevented infantile ophthalmia by washing the infant's eyes with filtered water immediately after birth, and then dropping into each eye one drop of a 2-per cent. solution of nitrate of silver with a rounded glass rod. The subsequent redness and swelling soon disappears. The ‘Credé Method’ has been adopted in the maternities of Berlin, Vienna, and Paris.”  
*Note.*—We presume that the term “Credé's Method” is applied simply to the routine employment of the nitrate of silver solution of this strength to all infants without waiting for the development of conjunctival symptoms. The good effects of nitrate of silver in such affections of the eyes is now a very old story. In the *Medical Press and Circular*, Feb. 20, 1884, p. 157, there is a note upon the instillation of a solution—strength, gr. j. to the ℥j. of water, hourly, in the conjunctivitis of the newly born, and of the excellent results obtained by John W. Martin, M.D., of Sheffield, in whose hands the practice was an old one when he wrote.

**ATROPINE IN ELECTRIC SHOCK.**—Dr. Wm. G. Eggleton, of Philadelphia, observes that the extreme cardiac and respiratory depression occasioned by the shock of lightning-stroke, or from the dynamo-electric machine, may be

effectually remedied by hypodermic injections of gr. 1-100 to 1-80 of atropine at intervals according to improvement, conjoined with brandy and ammonia.—*Ibid.*

**NEPHRECTOMY.**—Dr. Vincenzo Dattilo on the 8th March, 1885, performed a difficult operation of nephrectomy for suppurative pyelonephritis. The walls of the cyst could not be removed owing to extensive adhesions to the lumbar muscles, the diaphragm, and peritoneum. They were accordingly secured to the edges of the external wound by interrupted sutures. The cyst was previously evacuated eight times with Potin's apparatus, four pints of a purulent fluid being obtained at each evacuation. The operation, which was preceded by a ninth puncture with Potin's aspirator, and by free section of the twelfth rib, lasted forty minutes, and was conducted under strict antiseptic precautions. The highest temperature recorded subsequent to the operation was 100·4° F. On the 25th March the patient was rapidly recovering.—*Gazzetta degli Ospitali.*

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York by Messrs. WILLIAMS & ROGERS, Philadelphia, by Dr. BRINTON: post free in advance, 5½ dollars (£1 3s. 6d.) per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-Office Order.

## The Medical Press and Circular.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JULY 1, 1885.

### TO-MORROW'S ELECTION.

To-morrow (Thursday) the Fellows of the Royal College of Surgeons of England will decide by their votes who of the seven candidates for seats in the Council shall be chosen to occupy the three vacancies to be filled in that body; and at the same time an important indication will be afforded of the feeling among, at any rate, the metropolitan Fellows, in favour of a much-needed measure of reform. It must not, however, be too speedily assumed that the result of the poll will be a full indication of the sense of the majority in this respect, for so

long as present restrictions exist as to the facilities offered for the registration of votes, it must follow that not a few provincial Fellows willing and even anxious to record their votes will hesitate to incur the considerable expense in time and money necessary to this end, owing to the uncertainty whether their efforts may not after all be futile. Such an accident might very well happen under the rule which confers on the President of the College the power of closing the poll at any time, in case ten minutes shall elapse during which no single Fellow shall have registered his vote; for so long as this antiquated and indefensible regulation is in force, it is quite possible that a voter arriving from the country may not improbably find that all his sacrifices have been made in vain. Under all the circumstances it would not have been too much to expect that some intimation would have been given to the effect that this right would not be exercised on the present occasion; but in the absence of any suggestion of the kind, the risk has necessarily to be kept in view, and should be as far as possible guarded against.

We have already referred on more than one occasion to the candidates before the electors, and have shown how three of them, Messrs. Gant, Macnamara, and Pemberton, have definitely proved themselves worthy to receive the suffrages of all voters who are desirous of seeing the abolition of all the manifold abuses connected with the Council of the College. Of the remaining candidates, one, Mr. Savory, a retiring councillor, is the avowed champion of obstruction to the wishes of the body of Fellows and Members, he being unalterably determined to uphold the recent action of the Council in refusing to comply with reasonable requests preferred to it, and justifying its insulting attitude towards the two Associations pledged to bring about its reform. Three gentlemen, Messrs. Rouse, Mason, and Cowell, have not chosen to accept the public challenge held out to them to inform those whose votes they solicit on what grounds they base their claims to represent the Fellows on the Council, but we understand that an open statement has been made by one of them to the effect that he is in sympathy with the objects of the Association of Fellows. This proceeding, as a substitute for a straightforward exposition of policy, is most unsatisfactory; it affords no pledge for future conduct, and with the experience of last year to guide us, it suggests a most unpromising future, for it is still fresh in the minds of all how more than one nominal champion of reform, returned to the Council for the one purpose of preaching its purification, succumbed at the first available opportunity to the fatal influence at work within the chamber, and are now, in place of defending the views that they were supposed to uphold, joined with the most vigorous opponents of change in attacking the interests of those who trusted them not wisely but too well. This recollection will, we trust, exert a proper influence at the poll tomorrow, with the result that merely nominal reformers will meet with the fate their questionable sincerity richly merits. We need only urge further that any candidate for election to the Council who has not the courage to put himself irrevocably into a position he has publicly pledged himself to uphold, can only be relied on to swerve from the opinions that are alone valuable at the present

crisis; and we would once more repeat that, of all the candidates before the constituency, the three who have fulfilled their obligations in this connection, and so merited the confidence of the Fellows, are Messrs. Gant Macnamara, and Pemberton.

#### THE CASE OF DR. BRADLEY, OF BRIMINGTON.

THE miserable plight of our unhappy *confrère* Dr. Bradley has been again brought under the notice of the Home Secretary by Dr. Lyons, M.P., as well as by memorials from the medical practitioners of Derby and other places where the circumstances of the case are known, and by Dr. Ewing Whittle, of Liverpool, who has been in London, working up influence in favour of his release. It will be remembered that Dr. Bradley was prosecuted for rape on the wife of a collier, the transaction having been supposed to have taken place at 3 o'clock in a July afternoon in a ground-floor room off a crowded street, with both front and back doors open, the blind raised, and persons in the next room. Nevertheless, in consequence of Dr. Bradley's foolish confidence in his own innocence and his want of knowledge of the liability of the law to punish the wrong man, he was convicted of an indecent assault, and sent to jail by Judge Coleridge for two years and hard labour. Since then every means has been taken by his professional brethren to sift the evidence to satisfy themselves as to his previous character and to search out any evidence to prove his guilt, but the search for any incriminating circumstance, or any doubtful point in his character, has been in vain, and having taken every means of forming a just judgment, we entirely concur in the universal verdict of the profession that he is completely innocent of the crime for which he is suffering. Dr. Lyons, M.P., at our suggestion, has kindly made strong representations in the proper official quarters, but with no better success than is indicated in the following letter:—

Whitehall, 15th June, 1885.

SIR,—With reference to the application recently submitted by you, in behalf of the prisoner, David Bradley, I am directed by Secretary, Sir William Vernon Harcourt, to acquaint you that, after considering the whole of the circumstances of the case, and consulting the learned judge before whom it was tried, he regrets that he is unable to advise Her Majesty to interfere in the prisoner's behalf.

I am, Sir, your obedient servant,  
A. F. O. LIDDELL

R. D. Lyons, Esq., M.D., M.P.

Notwithstanding this assurance, we are very certain that the case has not been adequately considered by Sir William Harcourt, and we have very little confidence in the dictum of a judge who may be reasonably supposed to be very unwilling to admit the possibility of his having been wrong in sentencing an innocent man to so terrible a punishment as two years' hard labour. It happens that at the same Assizes at which Dr. Bradley was sentenced a man named Briggs was convicted and sent by Mr. Justice Coleridge to twenty years' penal servitude for poisoning his wife and son, but when doubts were thrown on the justice of the conviction, and a report obtained from a distinguished medical jurist, it turned out that

the unfortunate convict was quite innocent, and that if Mr. Justice Coleridge possessed any knowledge of forensic medicine he would have known that he was innocent. The man was at once pardoned (for being innocent), and the transaction kept as quiet as possible for the Lord Justice. If those who have undertaken to fight Dr. Bradley's case mean to succeed in restoring him to liberty and re-establishing his character, they must take much more vigorous steps than have hitherto been adopted, and having now satisfied themselves that paper and print produce very little effect on Home Secretaries and Judges, must arrange to have the matter forced upon the notice of Parliament.

We entertain not the least doubt that, if this be judiciously and energetically done—if the case be put plainly and briefly to members of the House, their opinion of it will be, overwhelmingly, in Dr. Bradley's favour; and if the opinion of the House be once aroused, we may anticipate that the new Home Secretary will evince a very lively interest in the case.

The following letter from Sir Joseph Neale McKenna, M.P., to Dr. Jeffreys, of Chesterfield, is encouraging evidence of the influence which such an effort might have:—

DR. JEFFREYS.

SIR,—I have received this morning the memorial of the medical practitioners of Sheffield addressed to the Home Secretary in the case of Doctor Bradley.

That memorial, in the absence of fraud on the part of those who have framed it and signed it, constitutes a body of evidence which no executive government can afford to disregard.

The Lord Chief Justice is a man of great eloquence and many accomplishments, but his individual opinion expressed at the trial of Doctor Bradley is not entitled to more unqualified respect than that which I have always paid to the opinion of the learned judge who tried Kilmartin, whose case came before the House of Commons on the 31st of July last.

Judges are not infallible. The Lord Lieutenant of Ireland subsequently saw fit to order an inquiry, and the result was that Kilmartin was released from penal servitude, and received a gracious pardon for the offence he had not committed.

I said when the case of Kilmartin was before the House of Commons that to my mind Kilmartin was as innocent of the crime of which a jury had convicted him, and for which a learned judge had sentenced him to penal servitude, as was the Chief Secretary (Mr. Trevelyan) who had just spoken on the case. I have no hesitation now in expressing an opinion on Dr. Bradley's case. I believe him to be as innocent of the offence of which he has been convicted and for which he suffers as the Home Secretary or the Lord Chief Justice.

But you must persevere with your remonstrance. The official and judicial mind is slow to receive impressions at variance with the dicta of judges and juries until you give evidence that they have exasperated the common sense and sense of justice of those who have better grounds for entertaining a strong opinion, on review of the case, than either judge or jury could have had at the trial on the case as then presented.

I am, &c.,

JOSEPH MCKENNA.

67 Lancaster Gate, London, W.  
20th June, 1885.

Dr. Bradley is, we are convinced, perfectly innocent. He is the victim of a felon's punishment, and hopelessly ruined in his profession. Is there no organisation to take his case in hand? Where now is the Parliamentary influence of the British Medical Association?

## Notes on Current Topics.

### The Microbe of Mumps.

THE researches which have already been instituted by MM. Capitan and Charrin on the microbes which are found in patients suffering from mumps have been further continued by M. Ollivier, who is said to have succeeded in discovering definite forms of micrococci in both the saliva and the urine of such subjects. These micrococci exist either singly, or united in pairs, or in the form of a zoogloea mass; and in addition to them the fluids examined contained the bacteria usually found in such excretions. The specific organisms, however, do not exist in the fluids obtained from persons in good health, and this fact is held to justify the theory that mumps is a disease of microbic origin, and by aid of which M. Ollivier is enabled to satisfactorily explain the phenomena it exhibits.

### Bad Meat.

SIR THOMAS DAKIN had before him on Friday last, at Guildhall, a dealer of Blandford, in Dorsetshire, who was charged with sending to the London market four quarters of a diseased cow unfit for human food. It appears the animal in question was drowned in a ditch, when its owner, a farmer, sold it to the defendant for £5, and the latter, after having it properly dressed, sent it for purpose of sale to the Metropolitan Market. In commenting on the facts of the case the worthy magistrate very rightly condemned the sending of bad meat to market as being constructive murder, since it was impossible to foresee the amount of injury that might not be occasioned by such proceeding. He proceeded to declare his resolution of sending to prison every one brought before him charged with this offence and proved to have committed it knowingly; but as in the case before him it was uncertain if defendant was really aware of the condition of the animal, he gave him the benefit of the doubt, and inflicted a fine instead.

### Curious Action of a Coroner.

ACCORDING to the newspaper reports of an inquest held a few days ago at Birkenhead, the course of action pursued in respect to it by the coroner presents a very curious aspect. The subject of the inquiry was a cellarman who fell and fractured his femur in March last. He was attended for more than two months by Dr. Butcher, whose practice is in the neighbourhood, and who is a member of the Birkenhead Borough Hospital staff. The deceased was a most unfavourable subject for such an injury, being of alcoholic habit, and was suffering from cerebral disease and arterial degeneration. Being in poor circumstances, and the treatment ordered by Dr. Butcher being greatly interfered with by meddling neighbours, the man was ultimately removed for better care and attendance into hospital, where he died from congestion of the lungs, his death being in no way remarkable when the circumstances are considered. An inquest was, however, held; and it is highly surprising to learn that Dr. Butcher's evidence was not only not requested, but was actually declined by the coroner, who elected to leave the case to the jury after they had heard a long series of

utterly valueless and inconsequent statements from a number of lay witnesses, many of whom appear to have been influenced by some special and ignorant animus against Dr. Butcher, whose treatment of the case seems to have met with the disapproval of the rabble. It is very much to be regretted that an officer holding the responsible position of coroner should permit himself to be influenced by the statements and prejudices of the unlettered mob, and doubly so when these so far prevail as to induce him to dispense with the only witnesses who are competent to give evidence as to causes of death, namely, medical men. We say nothing of the undignified attitude that non-medical coroners too often place themselves in by neglecting the plainest rules in this connection; the inference is too obvious. Dr. Butcher has our sympathy, and we feel assured that every right-minded reader of the facts of the case will at once appreciate his position, and regret for his sake that the inquiry was not more fittingly conducted.

#### The Small-pox in Dublin.

We are glad to learn that no extension of the small-pox has taken place in Dublin. The lady who brought the infection from England and the nurse died; the other lady is convalescent. With reference to our annotation of last week on this subject we think it right, in justice to the management of the Nursing Institute of the City of Dublin Hospital to say that the nurse sent to the case, though young, was experienced in fever. She had served a year and a-half in Sir Patrick Dun's Hospital, about a year in the Cork Street Fever Hospital, and three months in the City of Dublin Hospital, and, as she had been twice vaccinated, it was reasonably assumed that she would be as insensible to small-pox infection as any other nurse in the Institute. When the disease showed itself in her she was necessarily sent to the Cork Street Hospital because the family were leaving the infected house.

#### The Measure of Fidget.

UNDER the title "The Measure of Fidget," F. G. communicates a most original and interesting article to *Nature*, the subject of the paper being the study of "fidgetiness" in persons who are bored by an uninteresting lecture or similar performance. F. G. chanced to be present on such an occasion, and from his position at the back of the platform—unfavourable for hearing—he enjoyed an admirable opportunity for observing the effects of the lecturer's prosing on the audience. In his own words, "The feature that an instantaneous photograph, taken at any moment, would have most prominently displayed was the unequal horizontal interspace between head and head. When the audience is intent each person forgets his muscular weariness and skin discomfort, and he holds himself rigidly in the best position for seeing and hearing. As this is practically identical for persons who sit side by side, their bodies are parallel, and, again, as they sit at much the same distances apart, their heads are correspondingly equidistant. But when the audience is bored, the several individuals cease to forget themselves, and they begin to pay much attention to the discomforts attendant on

sitting long in the same position. They sway from side to side, each in his own way, and the interval between their faces which lie at the free end of the radius formed by their bodies with their seat as the centre of rotation varies greatly." F. G. further endeavours to apply a numerical standard of boredom, based on the number of movements made per minute by each individual, and his ingenious calculations well deserve to be made the forerunner of further observations. The whole subject is sufficiently novel to attract attention, and it is one of no inconsiderable interest, being capable of extension in many ways that will at once suggest themselves to the mind medical.

#### Enlargement of the Medical School of Trinity College, Dublin.

PLANS have been adopted by the Board of Trinity College for the erection of additions to the Medical School, which will cost about £14,000. An anatomical lecture-theatre, capable of accommodating over 300 students, is to be built.

#### Iodoform in Gout.

PROFESSOR TESTA (*Gazz. Med. di Torino*, 1885), having previously ascertained experimentally that iodoform fulfilled the requirements of a remedy for gout, i.e., that it accelerated oxydation processes within the system, increasing the excretion of urea, and diminishing that of uric acid and of oxalic acid, tried it in seven cases of gout and continued the use of the drug for months together. The dose varied from 7 to 25 cgrm. daily, given at twice. The remedy exercised on the whole a very favourable effect. The attacks became less frequent, and their intensity and duration were diminished. He thinks its use is contra-indicated, or at least, that it should be given with extreme caution, when the gout is complicated with kidney disease, as in case it is not duly eliminated by the kidneys, accumulation of it in the system might lead to serious results.

#### The Report of Experiments on Living Animals.

OUR contemporary the *Spectator*, although usually taking a fair and straight forward view on most matters connected with the profession, can hardly ever find a good word for anyone who may happen to differ from it on the question of "Experiments on Living Animals." Commenting on the annual meeting of the Anti-Vivisection Society last week, it impugns the *bona-fides* of the inspector's report, which it says, "is not so exhaustive as it should be." It is difficult to say what more should be said than what is said in the report. Mr. Bernard Coleridge, too, we are told, "showed that in many respects it did not tally with the facts reported in the medical journals," which means that it did not enable him to turn and twist the facts so as to place them in a sufficiently misleading way before his audience; while the evidence of "a great surgeon" is cited to show "how utterly inapplicable are experiments made on the livers of dogs to justify conclusions concerning the action of the human liver." "Tis pity 'tis true" that an "eminent surgeon," Mr. Lawson Tait, should have allied himself to

a society of fanatics who are determined to misrepresent the work and labours of men more eminent as physiologists than himself, and whose opinions on the subject have far more weight with the majority of surgeons. It is no doubt distasteful to "anti-vivisectionists" to learn from one who has the confidence of the profession and of men of science, Mr. Busk, "that the amount of direct and indirect suffering as the result of physiological and therapeutical experiments performed in England and Scotland under the Act in the year 1884 was wholly insignificant," as it has ever been before any Act came into force, and, therefore, that the ravings of the Bishop of Oxford "and other eminent speakers," were wholly uncalled for and out of place.

#### Early Menstruation.

A DR. DERVEER, writing to the *Gazetta Medica di Bahia* records a case of extremely early menstruation. The subject was an infant 2 years and 7 months old, who had menstruated from the age of four months, with the exception of a period of three months during which the menses did not appear. She exhibited symptoms of illness during the period they were absent, which disappeared on the return of the monthly flow. The child at the date of observation weighed 40 lbs. The mammae were the size of small apples, the mons Veneris, the labia majora and minora were well developed, and the former was covered with a growth of hair.

#### Antisepsis gone Mad.

AT Breslau a midwife was recently condemned to six weeks' imprisonment because she neglected to wash her hands in carbolic lotion immediately before commencing work in a case of confinement. The midwife said that she washed her hands in the carbolic wash before leaving her home; but this was declared unsatisfactory.

#### London Fever Hospital.

ON Tuesday evening last the festival dinner of the London Fever Hospital was held at Willis's Rooms, when a goodly number of influential gentlemen testified to their interest in this deserving charity by being present on the occasion and sharing in the proceedings. The Lord Mayor presided, and, at the close of the after-dinner speeches, the respectable sum of £2,517 was announced in donations and subscriptions. It is satisfactory to find that the claims of this important and essential institution are so well recognised, and that the heads of large business houses are alive to the privileges it offers to subscribers, as is shown by the long list of such names read out by the secretary. A fourth part of the annual outlay of the hospital is paid out of the contributions received from paying patients, a fact which is of itself an excellent sign, and at which wonder will not be felt when the admirable management of the place is reflected on, the arrangements for the care and comfort of the patients being perfect in every respect, while medically they could not be under more skilful or anxious hands. The mortality returns sufficiently prove the great care bestowed upon the cases, especially when it is remembered that very many of the patients are admitted in a most dangerous condition, needing that the utmost possible efforts shall be

made for their recovery. Indeed, the Fever Hospital provides a place of succour for the middle classes in time of infectious disease the value of which cannot be over-estimated, and deprivation of which would be one of the heaviest losses the community could endure. It is in every way worthy of support, and we trust the funds needed for the completion of the additional buildings will be at once forthcoming.

#### Pyridine for Asthma.

PROFESSOR GERMAIN SEE has recently laid before the Academy of Sciences some favourable results obtained in the employment of pyridine in the treatment of asthma. The best method of administration has been found to be by inhalation, which yields better results than either subcutaneous injections or the smoking of cigarettes saturated with the base (*Nouv. Rem.*, June, p. 121). For this purpose four or five grams are poured on a plate placed in a closed room. The air in this confined space being breathed by the patient, the pyridine rapidly passes into the blood, and its presence can be very soon after demonstrated in the urine. The patients are said to quickly experience a marked diminution of oppression, and the symptoms generally rapidly improve.

#### Proper Definitions.

THE following amusing story is going the round of the American medical journals, having first appeared in the *New York Medical Record*, and having arisen in connection with a certain celebrated suit in reference to the testamentary depositions of Miss Hoyt:—Dr. Millard testified that Miss Hoyt had many imaginary ailments, among them a belief that she had diphtheria and that she had coagulated blood upon the brain. The doctor testified that to humour her he called a professional cupper and leecher, a man named Hansen, who conducted an employment agency for nurses. This man bled her a trifle behind the ear, and then showed her a clot of blood on a plate, and she after that considered her head all right. "Did the nurse obtain the blood from her head?" General Butler asked. "He wasn't a nurse," answered the witness, "he only kept a nurse agency." "If he kept a nurse agency," returned the Massachusetts statesman, doggedly, "he was a nurse." "Then I suppose if a man keep a stable, he's a horse," suggested Senator Evarts, wearily. "Or if he drive an ice-waggon, he's a cold in the head," murmured Mr. Root, sadly.

#### A Practical Lesson on Dirt and Death.

THE town of Plymouth, in Pennsylvania, has been the scene of an epidemic of typhoid fever fearful in the extreme. Out of a population of some eight thousand about one-third have suffered from the disease. The local physicians have been unable to attend the sick, and so volunteers have been called for. The origin of the epidemic is clear. The town is situated on the alluvial soil of hills, which slope towards the river. The water supply has become polluted to an extreme degree, and Professor Kedzie reports it the very worst drinking water he ever examined. The town has no sewerage system. Hence, all the water polluted by being used for household and other purposes is left to find its own way

through the soil to the river. The epidemic seems to have been imported from Philadelphia. A person visiting that city contracted typhoid fever, and after his return to Plymouth the disease broke out. While sick he was in a house above the reservoirs, formed by damming the brook on its way through the town. From this water is distributed by pipes to most of the town. The excreta of this typhoid fever patient were carried by rains, melting snow, &c., into the brook, and so to the reservoir, whence it was widely distributed. In support of this view is adduced the fact that many of the families obtaining water from wells were not attacked by the disease.

#### Inefficacy of the Eucalyptus.

NOTWITHSTANDING the positive statements that have been made as to the suitability and value of plantations of *Eucalyptus globulus* in swampy and marshy districts, some scepticism has been manifested upon the point, and some time since a paper attributed anything but favourable results to the experiments made in this direction in Italy. In a recent report on the Lucknow Horticultural Gardens (*Gard. Chron.*) Dr. Bonavia records a similar experience and expresses a wonder that the tree should have ever been thought suited for the purpose.

#### The Scotch Preliminary Examination.

THE Colleges of Physicians and Surgeons of Edinburgh have given notice that after the 8th October next the preliminary examination hitherto conducted by them will be held by the Educational Institute of Scotland, whose examinations have been recognised by the General Medical Council.

#### Parenchymatous Injection of Fowler's Solution into a Leucæmic Hypertrophied Spleen.

THE *Deutsche Medicinal Zeitung* quotes the following from a paper by Dr. Peiper, of Greifswald:—In the course of eight weeks ten injections of a whole hypodermic syringeful of undiluted Fowler's solution were made into the spleen in a case of leucæmia. The patient bore the injections without any untoward symptoms. At first a decided diminution in the size of the tumour was noticed. It became hard, with a nodulated surface. Some weeks later a considerable diminution could be verified. The patient left the hospital some months afterwards decidedly improved. Such treatment is only recommended in the early stages of the affection, and before the tendency to hæmorrhage has become manifest.

#### Thalin Sulphate.

THIS drug has already been referred to in our columns as a reliable antipyretic. Amongst many who have already made trial of it may be mentioned Professor Landenberger, of the Katharinen-Spital Stuttgart, whose observations embrace over seventy cases. He reports that it brings about a reduction of temperature in all cases without any noteworthy undesirable bye-effects (cyanosis, collapse, &c.). According to the size of the dose the lowering of temperature lasts—three, five, or six hours, and the succeeding rise comes on slowly, so that the ori-

ginal temperature is not reached or passed for eight or ten hours. The dose varied from 0.25 grm. to 1 grm., 0.5 grm. being a medium dose. Wafers form a suitable vehicle for its administration. It may be procured from the B. Anilin and soda fabrik, Stuttgart.

#### Cholera Inoculation.

VERY little that is definite appears to have found its way into English journals regarding Dr. Ferran's inoculation for cholera. From a paper in the *El Siglo Medico*, June 7th, by Dr. Pulido, we get the following statistics, which will not be without interest. The town of Alcira contains 18,000 inhabitants: of these 9,874 were inoculated. The period of time to which the figures refer is the month of May:—

	Not Inoculated.	Inoculated.	Re-inoculated.
Attacked . . .	118	14	8
Recovered . . .	47	10	7
Died . . . . .	56	3	0
Under treatment	15	1	1

Three cases died within five days of inoculation before protection could be afforded by the procedure.—Town of Algemesi: inhabitants 7,856; inoculated 893:—

	Not Inoculated.	Inoculated.
Attacked . . .	263	8
Recovered . . .	186	7
Died . . . . .	32	1
Under treatment	35	0

Six died within five days of inoculation, and thus before the individual could be "protected." This reduces the number of those attacked after inoculation to 2, and one death was that of a child, who died on the seventh day of the disease, after refusing food throughout the sickness. The figures, if not absolutely unreliable, point to the necessity for thorough investigation. One fact mentioned by Dr. Pulido is significant, and quite sufficient to make one hesitate to pass through the ordeal of inoculation. He says, "Inoculation may cause death with symptoms of cholera."

#### The Franchise and Medical Relief.

THIS subject has been so exhaustively treated in these columns that we need only add the latest phase of development. On Sunday last Hyde Park was once more used for political purposes by a large concourse of persons, who met to protest against "the disqualification of voters by medical relief." It would be too much to expect that anything like a majority in so heterogeneous a mass understood the purposes of the meeting. Enough that there were bands and banners, that "the people were being put upon," and that the House of Lords said they should not vote if they got their medicine for nothing, which of course the Lords never thought of saying, but the professional agitators had a theme, and that was sufficient, and "Down with the House of Lords" was carried *nem. dis.* by thousands of the afflicted poor. One banner bore the following inscription:—"The Lords decree that if the people get sick they risk their votes. The people are sick of the Lords." Of course all this would be amusing were the public not being imposed upon; but it was ever thus.

By an announcement in another column it will be seen that the annual festival dinner of Volunteer surgeons will

take place in London on Wednesday next, at the Freemasons' Tavern, the Earl of Wemyss in the chair.

DR. JOSEPH EDWARD KENNY, Visiting Physician of the North Dublin Union, and Dr. Joseph R. Cardiff, of Carrigbyrne, co. Wexford, would, no doubt, think that we did them an injustice if we did not give them the advantage of publicly announcing that they have both ceased to be subscribers to this journal, alleging as their reason that they would not extend their valuable patronage to any periodical which expressed any disapproval of the recent insult to the Princess of Wales by a Dublin hospital surgeon, from whose house a black flag was hung while H.R.H. was passing. Our ex-patrons are entirely welcome to the credit of this little display of narrow-mindedness and intolerance, as it does us no harm, and we hope they may find the demonstration useful to them as a recommendation to their friends. Dr. Joseph Kenny is the gentleman whose battle we fought in these columns when he was (as we thought illegally) dismissed by the Irish Local Government Board.

### Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

EDINBURGH.—THE FEVER HOSPITAL QUESTION.—As previously mentioned in these columns, the authorities of the Royal Infirmary and the Sick Children's Hospital are to cease to receive into these institutions cases of infectious diseases after to-day (July 1). As the city authorities have now to provide for and control cases of infectious diseases, negotiations have been opened by them with a view to the purchase of the present Fever Hospital. In expectation of his, the managers have decided that if the Town Council make an offer of £4,000 for the grounds, buildings, and furnishing of the Hospital, the same would be accepted. This, it is explained, is very liberal on the part of the Infirmary Managers, as the Hospital with its equipment and the grounds in which it stands are worth about £10,500. The matter, it is hoped, will be satisfactorily settled to-day.

DEATH-RATE OF GLASGOW.—The mortality in Glasgow for the week ending with Saturday, the 20th ult., was 23 per 1,000 of the population, while in the previous week it was 24. In the corresponding weeks of 1884, 1883, and 1882 the rates were 25, 30, and 25 respectively.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 20th ult., the mortality in Edinburgh was 85, and the death-rate 18 per 1,000 per annum. Diseases of the chest accounted for at least 40 deaths, and zymotic causes for 9, of which 2 were due to fever, 1 to scarlatina, 3 to measles, 2 to whooping-cough, and 1 to erysipelas.

THE POLLUTION OF THE CLYDE.—The report of Dr. Wallace, city analyst for Glasgow, on the pollution of the Clyde through the discharge of offensive refuse from local works into the public sewers has been issued, giving analyses of the refuse water from various chemical works, tanneries, distilleries, refineries, slaughter-houses, &c. Of 45 samples analysed, 14 were alkaline, 18 acid, and 13 neutral; and the highest degree of alkalinity was equal to 958.7 grains per gallon of real soda, while the largest quantity of free acid was equal to 5,432 grains of hydrated sulphuric acid or oil of vitrol per gallon. The quantities

of waste liquids containing those enormous proportions of alkali and acid were, fortunately, comparatively small; but, on the other hand, there were samples containing considerable quantities of acid and alkali which represented large outflows. Dealing with the various cases, he recommends that in some instances the discharges into the river should be stopped altogether, and in others that they should be subjected to processes of purification. The quantity of refuse water sent into the river from the factories referred to in the report is given at nearly nine million gallons per day; and on the average it is said to be three times as strong in putrescible organic matter as ordinary Glasgow sewage.

### Correspondence.

#### THE UNCONTROLLABLE VOMITING OF PREGNANCY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR

SIR,—I shall be obliged if you will permit me to make one or two observations in reply to the remarks in the last number of the *Medical Press* on the uncontrollable vomiting of pregnancy. I am the last person in the world to deprecate criticism of my views on the subject in question, but I should like it to be exactly stated what my views really are, as it is evident there is a misconception in this particular.

From an analysis of thirty-two cases of so-called uncontrollable vomiting of pregnancy in which the condition of the uterus had been recorded, I argued that the cases "pointed conclusively to interference with the normal expansion and growth of the uterus" as the prominent pathological factor. Also, that "this is most frequently brought about by, or in connection with, detention of the bulk of the uterus in the bony pelvis," there having been in the large majority of cases incarceration of the body of the uterus in the pelvis in a state of ante flexion or anteversion; or, in a few instances, in a state of retroflexion or retroversion. Further, it is recorded that in certain other cases where no mention was made of displacement, there was particular mention made of presence of "hardness, resistance, unusual rigidity of the os and tissues of the cervix, and this abnormal condition extending to the internal os uteri."

From the above recorded facts I deduced the conclusion that "there appear to be two factors to be considered, both capable of interfering with the expansion of the uterus—A. Incarceration of the organ in the pelvis associated with flexion or version; and B. Undue hardness and rigidity of the tissues of the cervix around the os uteri internum."

The above quotations from my paper represent my views on the subject, and it will be evident from these paragraphs that I admit the possible occurrence of severe vomiting in pregnancy without actually present version or flexion. In another part of my paper I have expressed the opinion that the altered condition of the tissues of the cervix is mostly due to previous flexion or displacement, this latter opinion being, according to my experience, thoroughly supported by clinical facts. This latter opinion will, I confidently believe, come to be recognised as correct when the previous clinical history of cases is accurately investigated.

You rightly state that anteversion of the uterus "in early pregnancy may be, and in many cases certainly is, normal." But it is one thing for the uterus to be anteverted simply; and another for it to be anteverted and almost immovably fixed in that position in the pelvis. The latter condition, as is demonstrated by the cases I have collected, is one of the most frequently present conditions associated with uncontrollable vomiting in pregnancy.

It is not a little curious that Professor Horwitz, whose cases so completely support my views on the subject, expresses two absolutely opposite conclusions in his paper. In one place he says that I have over-estimated the frequency of alterations in the shape of the uterus in these cases, while in another part of the same paper he says "we have in most cases to deal with versions of the uterus, and sometimes to such a degree that the fundus uteri touches the symphysis, and is extremely difficult to redress; sometimes the uterus

appears to be wedged in the pelvis." The latter of the two opinions is further backed up by his statement that "he has been convinced by several observations that the direct redression of the uterus is the most beneficial measure that can be adopted." After this latter statement what are we to think of the value of the *first* expressed opinion?

Faithfully yours,

GRAILY HEWITT.

London, June 27, 1885.

#### THE COMING ELECTION AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you allow me to correct an important error in my letter which appeared in your impression of last week, an error which has just come to my knowledge, and which I am grateful for having had more accurate official information communicated to me, that now enables me at once to rectify it. I stated "that the office of Examiner in Surgery was restricted almost exclusively to members of the Council" of the College, whereas this is certainly not an absolute rule. As exceptions may be mentioned the present president and both the vice-presidents, each of whom was elected by the Council as an examiner in surgery before he became a member of Council, and the last two such examiners elected are not on the Council.

I feel that I ought to have ascertained these facts, or have remembered the more recent exceptions, before making a statement which, however, had reference to the principle of generally combining the two offices of examiner in surgery and member of the Council.

Trusting that you will insert this communication in your next impression,

I am, &c.,

FREDERICK JAMES GANT.

London, June 26th.

#### THE ALPINE TREATMENT OF CONSUMPTION. SEQUEL OF A CASE SENT TO DAVOS IN JANUARY, 1885.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Some time ago you were good enough to insert for me the narrative of the case of a patient who proceeded at my advice to Davos on January 4, 1885, being at that date 24 years of age. His mother had died of consumption, and two of his brothers died in early youth. The patient had, on January 4, a pulse of 130; there was dulness under the right clavicle, with bronchial breathing, and greatly-increased vocal resonance. The patient was very weak, and unfit for business. He proceeded at once to Davos at my advice, and lived there until June 4. During the month of January of this year there were, it seems, some twenty-three days without clouds at Davos, so that the patient, writing on Feb. 15, had had most favourable and most curative weather. The height of the barometer during January was from 25 inches to 24.20 inches, and the temperature varied from 50° F. to minus 1° F. There seems to have been very little wind in January, so that patients could walk out with very little clothing. Writing on March 13, he said he got out every day with very little inconvenience, and that he felt greatly better, his pulse having fallen to 76 and 80 when at rest, and his weight having increased 10 lbs. Dr. Ruedi, who saw him every now and then, said he was a "most promising patient," and, for his own part, he would not have known he was a patient were it not that he coughed occasionally.

On his return to London, this young gentleman resumed business on June 4, and came to see me on June 10. He said he could now walk some ten miles without fatigue. He did not sweat, and coughed only in the morning. On examination of the chest, I found scarcely any dulness under the right clavicle, and no rhonchus, but there was still considerable increase in the vocal resonance. Temperature was normal, and he felt quite equal for business, although he coughed and felt a little sickish in the morning. The improvement in this case was very marked, much more so, I think, than it would have been had the patient gone to Italy or the South of France, or taken a sea-voyage, although all of these treatments are occasionally, in my experience, very

curative of phthisis. I rather think the purity of the air at Davos and the dryness of the climate, conjoined with the low barometrical pressure, must be the main curative agents.

I am, Sir, yours, &c.,

23 Sackville St., London,

C. R. DRYSDALE, M.D.

June 16, 1885.

#### THE ROYAL UNIVERSITY AND ITS DEGREES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of June 10th, you publish a correspondence between the secretaries of this University and myself, together with some editorial remarks bearing on the two points at issue, viz., the evidence of study required from students for the degree of Master in Obstetrics and the surrender of the midwifery diploma by a Queen's University graduate on his receiving the M.A.O. of the Royal University. You agree with my contention that "attendances" are a farce, and bear no evidence of special study in obstetrics. I have suggested twenty "conductions"—you seem to think twelve would suffice, but though the actual number does not much matter, I would point out that students are required to *conduct* at least twenty cases of labour before being admitted to examination for the diploma of the Coombe Hospital. Surely it is not unreasonable when students can in this hospital always conduct the twenty cases without the slightest difficulty to expect that at least an equal evidence of competence should be required from a candidate for a University Degree.

With regard to the surrender and destruction of the Queen's University Midwifery Diplomas it does, at first sight, appear unwise to permit one individual to hold two diplomas, but these diplomas are not registrable, and therefore do not entitle the holder to practise midwifery. We must not, however, lose sight of the fact that the present question relates to a diploma furnished as an evidence of study for a *degree*, and therefore in the present instance there is no discussion on the judiciousness of a person being permitted to hold two diplomas; it is certainly strange that the apprehended danger has not occurred before the present time, although hundreds of medical men hold at least two diplomas. Surely it stands to reason that if this diploma is to be destroyed, the Senate, on their own rating, cannot as they contemplate, permit a graduate of the University to retain his M.B. diploma bearing the University seal, when he is granted the degree of Doctor in Medicine. A suggestion was made in the Senate by Mr. Farrelly, the senior representative of the graduates, to have the diploma perforated with the statement that the holder had been granted the degree of Master in Obstetrics, but this did not meet with the approbation of the majority. I should be glad, with your permission, to have these matters discussed in your columns, in order that I may bring the matter more forcibly before Convocation and the Senate, as it is a question of principle affecting a large number of graduates—especially as an Act of Parliament is at this present moment being promoted to make this degree and others of a similar character, registrable qualifications.

I am, Sir, yours, &c.,

CHARLES FREDERICK KNIGHT, M.D.

#### A NEW OBSTETRICAL SOCIETY FOR GLASGOW.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—If it is not out of order, perhaps you will allow me a few words in connection with the new Obstetrical and Gynaecological Society of Glasgow. Everyone who reads your paper values it for the valiant and independent spirit it habitually displays in the cause of truth, and we are glad of your reference to this society. The very general and almost universally favourable notice it has received is at least an indication that the establishment of it is a matter of interest. That there should be a diversity of opinion as to the necessity of its existence, however, *il va sans dire*. No two men think alike, and you are quite entitled to express your disapproval of this and any other society having for its object the study of any kind of speciality, such as an ophthalmic society, an aural society, and so on; and, of course, on the same kind of reasoning, there should be no Meteorological Society, nor Physical Society, nor Geographical Society, nor Statistical Society, nor, in fact, botanical,

geological, or astronomical society, because an old philosophical society takes in all the subjects *occasionally*. This kind of argument is, in fact, so all-embracing that it may very fairly be described as not-at-all-embracing, and as so deep as to have no bottom. All these kind of societies then being excluded or included by the same line of argument, they ought all to be very content.

So far, then, as this we are perfectly agreed, namely, agreed to differ. You say there is no use for our society, and we say there is, and that is an end of it. But, Sir, in so far as some assumptions in your notice are concerned, I beg respectfully and firmly to contradict you more at large. This society which was first mooted only in the beginning of May last, had its origin outside any gynaecological or any other fad. It was, in fact, a general practitioners' affair, and was so favourably regarded that within this short time (six weeks) forty-eight members have joined. You use the word "claquers" with regard to these, a word which is scarcely polite talking of your professional brethren, and you seem to think that a large body of men like this could be gathered together for the purpose of glorifying a few. I am sure you do not know them, else you would not think this, let alone write it. And as for worshipping, why, if one may conscientiously believe in the *orare est laborare maxim*, then this society intends to worship, *i.e.*, it intends to work. When I tell you, Sir, that one of its special rules is that work, attendance, communications, some kind of vital energy, shall require to be exhibited by every man to avoid exclusion, you will be able to see at once the kind of worship we intend to offer, and we will be glad to welcome all such worshippers. To, end, as for the other assumption that this new society may fan a mysterious kind of "pernicious flame," is there any more reason for saying this than that an ophthalmic society would spread diseases of the eye? I say on the other hand that disease and suffering and death (gynaecological or not) have nothing unusual or pernicious about them, but a terrible atmosphere of tragedy, which is sufficient to choke even indecorum. Why need you grumble at us preparing all kinds of weapons to fight these three enemies? *Honi soit qui mal y pense.*

I am, Sir, yours, &c.,

J. STUART NAIRNE.

Glasgow, June 26th.

## Special Correspondence.

### CHOLERA IN BURMAH.

[FROM AN OCCASIONAL CORRESPONDENT.]

WHILE the delegates of foreign governments at the Congress at Rome on the subject of cholera appear extremely eager to force ships from British India to submit to the delay and annoyance of quarantine, it may not be inopportune to point out where we may put our Anglo-Indian house in order. Cholera makes its appearance every year in Burmah; it is of frequent occurrence in Rangoon and Akyab. The authorities have to take immediate measures; alarming telegrams are at once sent to Europe, and the Italian and Spanish governments as a certainty declare quarantine against ships coming from the rice ports. The *Indian Pioneer Weekly Mail* just received in London contains a Rangoon telegram stating that the people about Pegu are dying of cholera by hundreds, faster than they can be buried. Although there may be some exaggeration, we find confirmation in the last Rangoon *Gazette Budget* of the 8th May. Fatal cases had occurred in Pegu in the end of April, and the disease had broken out in Rangoon, where there is a British garrison. On the 4th May, a Pegu correspondent reported cholera as raging there, with many deaths, adding that the grave diggers had run away, the magistrates were out in the district, and the corpses were lying unburied. Another person describes the disease as appearing in the district of Maoobin, where for the sake of a public ceremony the corpse of a priest was kept unburied for some days, to the danger of the resident inhabitants. No matter what the season, hot, cool, or wet, cholera is, however, never long absent from Burmah, and the foreign Consuls always let their governments hear about it.

The Burmans are superstitious, and after a few score of deaths occur, they get up propitiatory ceremonies, and

adopt what they consider spiritual means of driving the visitation out of their town. To adopt preventive sanitary measures they are little inclined, although the magistrates do what they can. But there are no natives trained as medical men in the European method; they know nothing of European systems of treatment of cholera or other diseases, and believe not only in frightfully large doses, but also in the efficacy of charms, and the remedy very often consists in incantations against witchcraft. The British Government has provided a few European Civil surgeons and a few natives of India who keep dispensaries. But these only touch a fringe of the population, and most of them cannot converse with the people in either the Madrases, Karen, or Burmese vernacular. What is wanted, and has been wanted for many years, is a supply of trained Burmese surgeons, or even compounders, who can teach and practise a reasonable and scientific system of medicine. Nothing has been done in this direction by the Department of Public Education except to offer a few scholarships at the Universities of India. A few Burmese have gone there, but the Government has been informed that as these gentlemen cannot pass the examination preliminary to B.A., the University will certainly refuse a medical degree. It appears that hardly any Burman has been able to get beyond the stage of matriculation.

This crude state of things has been exposed by the Rev. Dr. Strachan, M.D., Bishop of Rangoon, who is a qualified physician, and also by Mr. Jardine, the Judicial Commissioner, who has constantly to adjudicate on medical evidence in the Supreme Court. But as yet, neither the public instruction nor the Burmah medical authorities seem to heed the complaints of these gentlemen, and when public subscriptions to found scholarships were offered, these departments made no effort to collect them. Rangoon European surgeons, too, have pointed out another need of medical reform. It seems that any person, however ignorant, may practise as a physician and surgeon. There are no medical colleges, no test-examinations, and the law does not even require any practitioner to register his name. In this way, as the *Medical Press* has very recently pointed out, the really qualified medical man is exposed to a frightful competition, and the progress of medical knowledge is in every way delayed. The authorities have not treated Burmah, the home of cholera, as it deserves. The least that might be expected is, that when an epidemic breaks out, there should be a sufficient number of qualified medical men available on the spot to deal with the sick and the dying. But, in fact, their places are taken by the unqualified, the quack, and the dealer in incantations. We do not know whether these defects are known to Sir W. G. Hunter and Sir J. Fayerer, but we think that even without any suggestion from foreign governments, Lord Dufferin might direct the immediate organisation of a better state of medical arrangements than at present exists.

## Literature.

### HANDBOOK FOR THE INSTRUCTION OF ATTENDANTS ON THE INSANE. (a)

THE appearance of this little book marks a new departure in the field of lunacy practice. Few will affirm that the best is done for attendants that can be done; few will deny that they present one of the greatest problems with which lunacy administrators have to deal; and no one can conceive of lunacy treatment in its highest perfection apart from an ideal system of specially trained attendants. The object of the book before us is to form a stepping stone to this ideal system which we may only approximately reach, but which it is the duty of all asylum physicians to strive to reach. That the promoters of the handbook have prepared a perfect work we are not prepared to say; but that they have done what was required of them in large measure is certainly true. The idea is the product of a collective mind. The fructifying of the idea should have been entrusted to one, or at most two, individual minds. In the desire to meet the views of many, and in the arbitrary interference of a large committee, the risk of failure was great;

(a) "Handbook for the Instruction of Attendants on the Insane." Compiled by a Committee of the Psychological Association. London: Baillière, Tindall, and Cox. 1885.

but we are glad to find that in its completed form the work has not lost individuality, nor has the boiling down process of the committee interfered seriously with its integrity. Overlapping of the several sections one upon the other is manifest, but this is in some respects an advantage, as emphasising good points. The last chapter is a digest of asylum rules, and is perhaps too specialised for general use; but taken as a whole we are well satisfied with the result, and anticipate for it no small share of popular favour. The contributors are to be congratulated on their conscientious endeavour to reduce instruction to the simplest and most intelligible expressions, to that of concrete and not abstract subjects, and to uphold primarily the authority of the doctor in charge. The domain of medical treatment proper has not been trenchanted upon, the names and uses of medicines are conspicuous by their absence, and the dominant idea throughout has evidently been to stimulate observation and reflection, to increase the self-respect of attendants, to emphasise the intimate relations of body and mind, and to show insanity as a manifestation, not of temper, but of disease. A chapter is provided on mental nursing in private houses. The book is printed in excellent type, on good paper, and is bound in cloth. Side notes are lavishly supplied, and the price is so moderate as to bring it within the reach of all attendants and nurses.

#### GOUT, RHEUMATISM, AND THE ALLIED AFFECTIONS. (a)

DR. HOOD is a practitioner, not a teacher in a medical school, and writes accordingly. He commences with a preface which is written under the inspiration of sound good sense. He in it points out that in his education the student is instructed about diseases; but it is only after entering practice he finds that he has to deal with "the sick man." This is a new factor he finds. Certainly this is true about gout and gouty persons. It is well to treat the gout, doubtless; but in order to do so successfully the individual in whom the gout shows itself has to be borne in mind. Dr. Hood states boldly: "I have sometimes stated and assumed doctrines in support of which I can adduce no chemical or physiological experiments, but which have been slowly formed amidst the work of healing, and which are deeply graven on my mind by the finger of time." And the reader will find as he reads that Dr. Hood will exhibit on alternate pages a decided want of acquaintance with the modern scientific knowledge pertaining to medicine, together with an exceedingly shrewd practical knowledge of the treatment of disease. He leads off with some remarks upon historical personages, as Henry VIII. and the Emperor Charles V., both of whom were decidedly gouty, and both of whom were large meat-eaters—remarks not at all out of place. Then he follows with quotations from authorities on gout all useful. That he has seen much of gout is obvious from the manner in which he handles the subject. He states: "Of all remedies for the prevention and cure of gout, next to judicious abstinence, there is none equal to exercise," a sentence which speaks for itself. Those who are inclined to resort recklessly to colchicum in the treatment of acute gout will find some very instructive pages in this little work. Those who have not learned the value of calomel in its place will also learn something of value to them, and still more to their patients. It is not a systematic treatise like the works of Garrod and Milner Fothergill, but it is a book well worth perusal; especially by young practitioners who are beginning to make the acquaintance of gouty patients in a good social position. Such readers will profit by what they read, or at least ought to do so. They will learn, if they did not know it before, that gout is not simply a disease of the articulations. Then follows a dissertation on rheumatism well worth reading. A chapter on Longevity is interesting. The work concludes with an essay on Sleep, which is instructive, though scarcely abreast the time. Of the work as a whole it may be said that it is just such a book as might be expected from a shrewd, observant, old practitioner (and containing much worth knowing not taught at medical schools), who kept abreast of the literature of his own day, though not equally familiar with recent matter.

(a) "A Treatise on Gout, Rheumatism, and the Allied Affections," by Peter Hood, M.D. Third Edition. London: J. and A. Churchill. Pp. 406.

#### INDEX CATALOGUE. (a)

WE have examined with interest the columns of this large tome, which gives us further insight into the medico-literary treasures of the magnificent library which the wise munificence of the U.S. Government is collecting for the use of her "army medical department." The perusal, be it candidly confessed, excited in us feelings somewhat related to envy, as we feel that we ourselves can but seldom have the opportunity of indulging in the sweets afforded by a temporary visit to so magnificent a collection of the curious and the valuable in medical and surgical literature. We feel assured that no pains have been spared in bringing such a collection together, and it is well known among book-fanciers that money is no object with brother Jonathan when a rare article in the bibliographical department has to be secured. Accordingly his libraries are fast coming to supersede in value any of our European treasures. It is known to everybody that at the late sale of the Syston Park Library, biblio-maniacism reached the highest point to which it has yet attained in estimating the comparative values of gold and printed vellum. But it is not so generally known that on securing the most prized article there presented to the eager eyes of competitors, the prince of antiquarian booksellers at once hastened to communicate his success, per Atlantic cable, to a well-known New York banker, whose tastes and outlay in matters bibliographical have long been of the most princely character. The telegram contained an invitation to secure the volume at a fixed profit. A prompt reply from the other side informed the dealer that his American cousin had been for some time blessed in the possession of the best conditioned specimen of this variety now known to exist, and accordingly, did not think it necessary to consider a new offer. The volume has accordingly been catalogued—with what result we know not. Purchasers, such as that above referred to, are not rare in the United States, and the fact sufficiently explains the vast treasures of biblical wealth, in all its departments which are rapidly accumulating there, and which make a well-prepared catalogue of any of the larger collections of that country extremely instructive and interesting to the curious among the inhabitants of the old world.

The catalogue which we have on our table is a favourable specimen, and will well repay examination. An occasional peep into its pages will always be found to give interesting information about volumes whose contents can be advantageously consulted by many of the intensely "practical" men who seem rather proud of their non-acquaintance with the opinions of their professional ancestors.

#### Medical News.

**University of Oxford.**—At a congregation holden on June 18 the following degrees were conferred:—

DOCTOR OF MEDICINE.—J. Price, Queen's;  
BACHELOR OF MEDICINE.—F. Phillips, Balliol; R. Ward, Exeter;  
G. Buckmaster, Magdalen; A. Garrod, A. Greswell, A. Orr, Christ-Church; L. Guilding, Worcester.

**University of Cambridge.**—At a congregation holden on June 17 the following degrees were conferred:—

BACHELOR OF MEDICINE.—Samuel Herbert Habershon and Thomas George Styau, Trinity; Patrick Cumin Scott, St. John's; Thomas Ernest Hillier and Frederick Charles Wallis, Gonville and Caius; Sidney Morton Pearson Roberts, Christ's; Edward Waymouth Reid, Cavendish.

BACHELOR OF SURGERY.—Frederick Charles Wallis, Gonville and Caius; Sidney Morton Pearson Roberts, Christ's.

**University of Durham.**—Pass Lists in the Faculty of Medicine for the Easter Term, 1885. The following satisfied the examiners:—

 Walker, Charles Pope, M.R.C.S.

**Royal College of Surgeons in Ireland.**—The following gentleman was admitted a Fellow on June 19:—

G. B. White, A.B.

The Council has elected Mr. S. Webb an additional Examiner in Physics, Chemistry, and Medical Jurisprudence.

**Royal College of Surgeons of England.**—The following gentlemen, having undergone all the necessary examinations, were admitted Licentiates in Dental Surgery at a meeting of the Board of Examiners on June 24:—

Bardet, Paul Charles Albert	Mackrell, Alfred Sextus
Campion, George Goring	Mugford, George Henry
England, Walter Joseph	Peah, Frederick Snell
Gabriel, William Maurice	Robinson, Arthur Bernard
Goffe, Frank Hampton	Smith, Charles Robert
Jones, Alexander John	Williams, Hugh Lloyd.

**West London Medico-Chirurgical Society.**—The annual meeting of this Society took place on Friday, June 19th, with Mr. Lawrance, President, in the chair, when the annual report was read, showing that the Society was increasing in numbers and in a perfectly satisfactory financial position. Mr. Hemming was elected President for the ensuing year, and Drs. Alderson, Pickett, Barnes, and Campbell Pope were elected Vice-Presidents. Mr. Lawrance will succeed Mr. Alfred Cooper as Treasurer, and Mr. Percy Dunn takes Dr. Campbell Pope's post as one of the Secretaries. Votes of thanks were passed to the various officers retiring for their services during the past session, and Mr. Lawrance, after introducing his successor in the presidential chair, thanked the members of the Society in a few brief words for their courtesy and kindness during his term of office.

**Conversazione at the Middlesex Hospital.**—A most successful conversazione, organised by the President and Officers of the Students' Medical Society, was held at the Middlesex Hospital on Thursday evening. In spite of the somewhat unseasonable weather a fashionable assemblage of ladies and gentlemen, numbering at least two thousand, collected within the precincts of the hospital, and enjoyed to the full the various artistic and scientific amusements provided. The board-room and new out-patient department were exquisitely decorated, and proved admirably suited for the reception of the guests and for the exhibition of the various objects of scientific interest kindly lent by most of the leading firms. But the special feature of the evening was the brilliant yet tasteful illumination of the spacious gardens of the hospital. An excellent musical entertainment, under the direction of Mr. G. A. Osborne, was provided in the school, to which Mr. W. H. Cummings and other eminent artistes lent their valuable assistance. In the Anatomical Theatre, which was filled to overflowing, Dr. B. W. Richardson, F.R.S., delivered a most interesting address on "Medical Poets." The lecturer began by observing that Apollo was the god of Physic as well as of Music and Song, and it was natural therefore that men of physic should combine the two arts. No profession had produced so many poets as medicine. Of what might be called prose poets brilliant examples were such men as William Harvey, Arbuthnot, William Hunter, Sir Thomas Watson (who had taught the practice of medicine in the Middlesex Hospital School), John Fernandes Clarke, Mr. Stephens, of Finchley, and others. Among poets of fame who had been more or less connected with the practice of medicine, he instanced Sir Thomas Browne, the author of the "Religio Medici," Sir Richard Blackmore, Sir Samuel Garth, Mark Akenside, John Armstrong, Oliver Goldsmith, Erasmus Darwin (the grandfather of the late Charles Darwin), Nathaniel Coltar, George Crabbe, David Muir, and John Keats. From each of these authors Dr. Richardson gave choice extracts, and at the conclusion of the address a hearty vote of thanks was accorded to him. The band of Messrs. Lucas played a charming selection of music in the

gallery of the museum during the evening. Altogether the entertainment was an unqualified success.

**Queen's College, Cork.**—The following prizes have been awarded in the Faculty of Medicine:—Practical Anatomy—1st, J. W. Wolfe; 2nd, John Jackson; 3rd, P. P. Jennings. Certificate, J. V. Ryan. Chemistry—J. W. Wolfe. Zoology and Botany—J. W. Wolfe. The following prizes and certificates have been awarded in the classes of Practical Chemistry and Materia Medica, instead of those formerly awarded, which have been cancelled:—Practical Chemistry—1st, W. J. O'Meara; 3rd, R. J. Duffin; 4th, E. R. Hennessy. Certificates of Honour—D. J. O'Mahony, M. J. O'Regan, and Francis John Perrott (equal). Materia Medica—1st, R. J. Duffin; 2nd, Daniel O'Callaghan; 3rd, E. R. Hennessy. Certificate of Honour—John T. Walsh. The exhibition in Practical Midwifery has been obtained by Daniel Lane.

**The Mortality of Foreign Cities.**—The annual death-rates per 1,000 in the principal foreign cities, according to the last weekly returns communicated to the Registrar-General, are as follow:—Calcutta 25, Bombay 26, Madras 33, Paris 23, Geneva 16, Brussels 19, Amsterdam 21, Rotterdam 19, The Hague 21, Copenhagen 22, Stockholm 30, Christiania 24, St. Petersburg 29, Berlin 24, Hamburg 25, Dresden 25, Breslau 30, Munich 30, Vienna 30, Prague 40, Buda-Pesth 30, Trieste 27, Rome 22, Turin 24, Venice 29, Alexandria 31, New York 25, Brooklyn 20, Philadelphia 19, and Baltimore 15.

**Vital Statistics.**—The deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 18.3 per 1,000 of their population, and were—Birkenhead 19, Birmingham 19, Blackburn 25, Bolton 21, Bradford 16, Brighton 15, Bristol 15, Cardiff 31, Derby 10, Dublin 27, Edinburgh 18, Glasgow 22, Halifax 14, Huddersfield 22, Hull 17, Leeds 17, Leicester 15, Liverpool 23, London 16, Manchester 25, Newcastle-on-Tyne 24, Norwich 18, Nottingham 21, Oldham 18, Plymouth 20, Portsmouth 13, Preston 20, Salford 22, Sheffield 20, Sunderland 17, Wolverhampton 13. The highest annual death-rates from diseases of the zymotic class in these towns were—From measles, 2.6 in Salford, 2.7 in Liverpool, 3.4 in Birkenhead, and 5.1 in Newcastle-upon-Tyne; from whooping-cough, 2.2 in Cardiff, 2.7 in Plymouth and 5.6 in Blackburn; from scarlet fever, 1.0 in Preston, and 1.3 in Wolverhampton; and from "fever," 1.1 in Norwich, 1.2 in Portsmouth, and 1.6 in Cardiff. The 26 deaths from diphtheria included 16 in London, 3 in Liverpool, 2 in Sunderland, and 2 in Cardiff. Small-pox caused 32 deaths in London and its outer ring, 2 in Hull, and 1 each in Dublin, Glasgow, and Manchester.

**University of Edinburgh.—Final Examinator in Medicine.**—Dr. Bristowe, Mr. Holden, and Dr. George Kidd, of Dublin, have just visited Edinburgh as Commissioners from the General Medical Council, to inquire into the system of teaching and examination in the medical schools. They had an opportunity of being present at the final examination for Graduates in Medicine. It is announced that the following gentlemen have passed:—Messrs. Arthur Russell Aldridge, Robert Thomas Allen, James Anderson, John A. Ashcroft, John Mackintosh Balfour (with distinction), Robt. Beveridge John Wilson Black, Robert Bone, George Lindsay Bonnar, Louis Jules Henry Bouchet, Edward Kemp Bourne, Reginald Bowman, Herbert Brooks, Harbit Brown, Walter Burns, William Johnstone Cameron, Edward Chamberlayne, Clifton Charleton (with distinction), Reginald Chetham-Strode, Richard Davidson, M.A., David Middleton Greig, Joseph Griffiths, Samuel Hughes, George Francis Johnston, John Charles Lamont (with distinction), Edward Leonard Lees, William Robert M'Kinnell, Charles Henderson Melville, Edwin Morton, Edward Joseph B. du Moulin (with distinction), Ernest Robertson, Herbert Shelmerdine, William Henry George Stephen, Caleb Terrey, William James Thomas, Henry Alexis Thomson, John Warnock, Fitzgerald George Westema, Henry Worsley.

## Notices to Correspondents.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**READING CASES.**—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

**LOCAL REPORTS AND NEWS.**—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

**HEALTH OFFICER.**—The population of Madrid is officially given as 475,000. About half a million, we believe, more nearly represents the number.

**DR. JULIUS ALTHAUS.**—Your "Case of Brain Syphilis" is marked for an early number.

**DR. SCHOFIELD (Kensington).**—We hope to find space for the letter in our next.

**MR. DOWNES (Notting Hill).**—We do not give the addresses of medical men for consultation in these columns. You will find that of the gentleman referred to in your note in the London Medical Directory.

**MR. SUNTER (Charlton).**—During the months of June and July only.

**MEDICAL WITNESS.**—The coroner is bound by the 27th section of the Coroners Act to call as his witness a "duly qualified practitioner being at the time in actual practice at or near the place." This definition was substituted for the phrase used in the original Act, which compelled the medical attendant of the deceased to attend, and it is manifestly intended by the law that the practitioner who last saw the patient should be called to testify. If there was no such last attendant the coroner may call anyone "practising at or near the place," but if his assistant does not answer to such definition, the payment of a fee to him is illegal, and may be disputed when the coroner's fees come to be stated at the Assizes.

**W. G. E.**—We shall be glad to have an opportunity of inspecting the works, and willingly undertake to fulfil all the conditions named. We will arrange for the consideration of every problem in accordance with the terms proposed in the letter.

#### RIVAL QUACKS.

THAT well-worn truism, "When thieves fall out, honest men come by their own" was fully borne out last week at Hanley, in Staffordshire, when two "professors of the healing art," sine diplomas, quarrelled as to their methods of carrying on "practice." As one appeared to the other to be getting the lion's share, he adopted the device of advertising himself by treacled buns and other luxuries to a given number of boys. Quack number two considered this method of his learned brother unprofessional, and published a libellous circular in consequence. Number one thereupon carried the matter to the law courts, when the magistrate properly decided that, as neither had any legal status, they might expose each other to their heart's content, but libelling was impossible, as they had both placed themselves beyond the protection of the law. The profession in Hanley has been much edified by the scene, and the public are learning the true character of the combatants.

**MR. CARMICHAEL.**—Such eruptions are of common occurrence in children of that age, and, as a rule, they have their origin in some slight disturbance of the digestive functions, usually associated with teething. The treatment you have followed is very good, but in order to allay irritation of the "lumps" a solution of borax, almost saturated, will be found most useful.

**CÆLUS.**—A full account of the operation and all its requirements will be found in "Bryant's Surgery," 4th edition, vol. II, together with illustrations of the instruments employed. Sir Henry Thompson's work also contains a complete description of the proceeding, with an account of the improvements introduced by himself, and notes of numerous cases in which he has carried out the operation with signal success.

**DR. FINCH.**—The entire programme will be published in this country as soon as all the arrangements for the Congress have been finally settled. There is no doubt that exceptional facilities for crossing the ocean at a reduced cost will be afforded to European members of the Congress; and it is certain also that these will meet with a most hearty welcome from their American brethren.

**DR. WHITNEY.**—We do not remember ever to have seen the recipe before. There is, however, nothing in it of a particularly startling character. It seems to be little more than a mildly stimulating expectorant mixture. It certainly contains nothing that could sustain the claim which you say is made on its behalf.

**MR. SINGLETON.**—You had better consult the Secretary of the institution, who is the right person to afford the information for which you ask. We are not in a position to recommend this or any other piece of like character, since we have never been at the trouble to inspect them with a view to advising on them. It is but right, however, to add that we have no reason for thinking they are conducted in any other than a thoroughly satisfactory manner.

**O. D.**—Such a scheme could never have a chance of succeeding. It is impracticable.

#### MADEIRA.

THE Union Line (Royal Mail Service) asks us to announce for the information of those of our readers who may recommend patients to visit Madeira for their health, or who may themselves have occasion to visit that island, that from and after 1st July a considerable reduction in the passenger fares from Southampton or Plymouth by the steamers of the Union Steamship Company will be made, the directors of that Company having decided to reduce the outward fares from 15 guineas 1st class, 12 guineas 2nd class, and 10 guineas 3rd class, to 15, 10, and 7 guineas respectively, the homeward fares remaining as at present—viz., 12, 8, and 6 guineas respectively. The passage money to and from Madeira includes railway fare between London and Southampton, or vice versa.

#### PROFESSIONAL ETIQUETTE.

J. H. says: A doctor is called to a patient whom he has been treating at different times for the past twenty years. Owing to having discontinued country practice he refuses to go, but (without consulting the patient) sends another practitioner. The substitute is not cared for, and the patient discontinues his attendance after one visit and sends for one of his own choosing. Is the latter in any way acting contrary to professional etiquette in coming?

[Certainly not. The patient is fully entitled to choose his adviser, and there is not the least reason why the adviser should wait upon the convenience of anyone except the practitioner who is actually in attendance at the time.—ED.]

## Meetings of the Societies.

WEDNESDAY, JULY 1ST.

**OBSTETRICAL SOCIETY OF LONDON.**—At 8 p.m., Specimens will be shown.—Dr. Priestley, Notes of a Visit to some of the Lying-in Hospitals in the North of Europe, and particularly on the Advantages of the Antiseptic System in Obstetric Practice.—Dr. Herman, On the Suppuration of Pelvic Dermoid Cysts.—Mr. Hine, Case of Obstructed Labour in which Spontaneous Version followed an unsuccessful attempt to Deliver by the Crotchet after Craniotomy.

FRIDAY, JULY 3RD.

**OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.**—At 8 p.m., Living Specimens.—8.30 p.m. Discussion on the President's paper on Reflex Ophthalmitis.—Mr. Anderson Critchett, Case of Extreme Retinal Irritability.—Mr. J. B. Lawford, Tubercle of Choroid.—Messrs. Walter Edmunds and J. B. Lawford, Pathological Anatomy of Optic Neuritis.

## Vacancies.

Chelsea Hospital for Women, Fulham Road, S.W.—Resident Medical Officer. Salary, £60 per year, with board and residence. Applications to the Secretary by July 6.

Hants County Asylum.—Junior Assistant Medical Officer. Salary, £100 per annum, with board, &c. Applications, with testimonials, not later than July 8.

Salop and Montgomery Counties' Lunatic Asylum, Shrewsbury.—Junior Assistant Medical Officer. Salary, £100 per annum, with board, &c. Applications, with testimonials, to the Medical Superintendent, on or before July 8.

Sussex County Hospital, Brighton.—Assistant House Surgeon. Salary, £40 per annum, with board, &c. Applications, with testimonials, to the Secretary, on or before July 15.

## Appointments.

BAILEY, W. H., M.R.C.S., House Surgeon and Secretary to the Newark Hospital and Dispensary.

CLENNIHAN, J. G., L.R.C.S.I., Medical Officer for the Third Sedgeley District of the Dudley Union.

DRAPER, J. W., M.R.C.S., L.S.A. Lond., Medical Officer for the Almondbury District of the Huddersfield Union.

FINEGAN, A., L.K.Q.C.P.I., Medical Superintendent of the County Mayo Asylum, Castlebar, Ireland.

GRIFFITHS, W. G., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the Llanwilio District of the Carmarthen Union.

LEIGH, W. W., L.R.C.P. Ed., M.R.C.S., Medical Officer for the Gellygaer District of the Merthyr Tydvil Union.

MILLER, W. F., M.B., M.R.C.S., L.R.C.P. Ed., L.R.C.S. Ed., Health Officer for Carisbrook, Victoria.

MORRIS, C. A., M.A., M.B., B.C. Cantab., M.R.C.S., Resident Medical Officer to the Liverpool Royal Infirmary.

ROYDS, W. A. S., L.R.C.P., M.R.C.S., Surgeon to the Royal Berkshire Hospital.

## Births.

POWELL.—June 25, at Blyton House, Weybridge, the wife of John Powell, L.R.C.P. Lond., of a son, stillborn.

STRADLING.—June 22, at Flores, Watford, Herts, the wife of Arthur Stradling, M.R.C.S.E., &c., of a son.

## Marriages.

MCMANUS—BOYD.—June 24, at St. James's Church, Dublin, Leonard Strong McManus, M.D., M.Ch., of New Wandsworth, London, to Julia Emily, second daughter of Robert Macroy Boyd, of Walsworth.

MORRIS—KING.—June 22, at the Cathedral, Marlborough Street, Dublin, James A. Morris, L.R.C.S.I., L.K.Q.C.P.I., Kilderry House, Co. Kilkenny, to Mary, eldest daughter of the late John P. King, Esq., Cogner House, Co. Louth.

WINDLEY—HILL.—June 24, at St. Mary's Episcopal Church, Glasgow, William Windley, M.R.C.S., Nottingham, to Barbara Katherine, second daughter of Laurence Hill, C.E., Glasgow.

## Deaths.

DANE.—June 21, suddenly, at his residence, Finchley Road, South Hampstead, Thomas Dane, M.R.C.S., aged 51.

HEBLOP.—June 17, whilst travelling, suddenly, in Scotland, Thomas Prestious Heblop, M.D., F.R.C.P., of Birmingham.

FRATER.—June 20, at 28 Devonshire Street, London, W., Horatio Frater, M.D., of Kensington, aged 79.

STACE.—June 15, at Abu Zaimah, Soudan, of enteric fever, Arthur Frank Stace, Surgeon Army Medical Staff, aged 24.

## Original Communications.

### SOME POINTS IN THE TREATMENT OF UTERINE FIBRO-MYOMATA. (a)

By THOMAS MORE MADDEN, M.D., F.R.C.S.E.,

Obstetric Physician Mater Misericordias Hospital, Physician to the Hospital for Sick Children, Dublin, Consulting Gynaecologist Dublin Provident Infirmary, formerly Examiner in Obstetric Medicine and Gynaecology Queen's University in Ireland, Vice-President British Gynaecological Society, Consultant National Lying in Hospital, &c.

As the respective merits of the various operations now employed in the treatment of fibro-myomata are still *sub judice*, I venture to submit some observations on the methods of dealing with these tumours, of which I have had clinical experience in my hospital practice. My chief purpose in so doing is the hope of thus eliciting the views of other gynaecologists of larger experience on a subject always of practical importance, but which, owing to recent strenuous advocacy of abdominal section in such cases, is of special interest at the present time.

In considering the treatment of uterine fibromata, it should not be lost sight of that every growth of this kind is primarily an interstitial myoma, which in the course of time becomes more or less fibrous in structure by the development of its connective tissue, and which by its gradual increase of size may eventually be either subperitoneal or submucous. Hence the operative treatment required in those cases in which any surgical interference is necessary should be mainly determined by the size and position of the neoplasm, rendering removal most feasible either per vaginam or by abdominal section. According to my own experience the former is more generally possible, even in the case of interstitial fibroids, than is generally conceded. At the same time, being a believer in the advantages of hysterectomy and oophorectomy by abdominal section for fibromata, otherwise beyond the reach of gynæ-

cological assistance, I am desirous to obtain some expression of opinion as to the limitations which should be imposed on the procedures. For if the operative zeal now evinced in the performance of abdominal sections by some eminent surgeons be allowed to develop much further without protest, the legitimate employment of these procedures will be largely prejudiced by the inevitable reaction of opinion against such operations. It seems to be entirely ignored by some of those who urge the early and general performance of abdominal operations for fibromata, that in the majority of cases these tumours may be as effectually dealt with by less hazardous procedures, and that in very many instances they demand no operative interference whatever.

As to the possibility of the spontaneous cure of fibromata by absorption and their occasional diminution under medical treatment, there can be no question. I have myself elsewhere recorded cases in which such tumours had been thus notably reduced in size, and many well authenticated instances of their complete subsidence in this way have been related.

Amongst these a very remarkable case has been narrated by Dr. Kidd ("Dublin Obstetrical Transactions," vol. v.), in which a large uterine fibroid, that at one time occupied the whole of the upper part of the pelvis and rose in the abdomen midway between the umbilicus and xyploid cartilage, was within a period of five years completely removed by absorption as to leave no trace whatever of its former existence.

The probability of such a termination in any individual instance is, however, too remote to have any material influence on the general prognosis and treatment of such cases. Still, its possibility is a fact which must not be altogether lost sight of.

We may now briefly consider the advisability of abdominal operations in cases of fibromata. Secondly, I shall say a few words with regard to the less heroic measures, such as enucleation and "removal by traction," which may, in many instances, be resorted to in place of the bolder operation just mentioned. And, lastly, I shall allude to the too generally neglected medical treatment

(a) Paper read before the British Gynaecological Society, May 13.

of such cases. With regard to the first named of these methods, I may here refer briefly to some observations I have recently made on this subject.

The cases of fibromata requiring either hysterectomy or oöphorectomy which have come under my own observation in the course of a gynecological experience of upwards of fifteen years in the two hospitals with which I have been connected have been, comparatively, few and far between. Hence I cannot but think that the enormous proportion of such cases met with in the practice of other surgeons must, in some degree at least, be the self-created result of the preconceived views of those who now find these operations so generally necessary; and may be traceable to the analogy instituted between uterine and ovarian tumours. The successful results of the removal of the latter have, however, no bearing on the question of abdominal operations in the treatment of the former. Not alone are the risks of the one infinitely greater than those of the other, but even if they were equal the conditions for which they are resorted to are so essentially dissimilar, that there can be no parity in their treatment. Ovarian tumours, if left to nature, are, as a rule, rapidly progressive in their course, and ultimately eventuate fatally. Not so uterine fibromata, which, however much discomfort, suffering, hæmorrhagic discharge, and impairment of health they may occasion, seldom if ever directly destroy life, and in the majority of cases become arrested in their development and symptoms by the changes consequent on the menopause. Therefore, the amount of risk justifiable in the removal of an ovarian growth is not necessarily justifiable in the case of a uterine neoplasm.

In my own practice I have never hesitated to recommend oöphorectomy, or hysterectomy if required, in cases of subperitoneal and deep-seated interstitial fibromata, in which the tumour was not accessible per vias naturales, and in which the age and condition of the patient, the rapid rate of development of the neoplasm, or the urgency of the resulting symptoms, were such as to preclude the hope that in the course of time the disease might be arrested by the occurrence of the menopause. Moreover, in the case of a young woman of the class generally met with in hospital practice, to whom the suffering and loss of physical strength consequent on such a tumour would entail privation of the patient's means of living; if she be willing to encounter the risk of an abdominal section, we are, I think, if the case be otherwise suitable for the operation, bound to afford her the chance of its successful performance. The advocates of oöphorectomy and hysterectomy however apparently take a much larger view of the utility of these operations in such cases. For instance, in Mr. Lawson Tait's recent "Address on One Thousand Abdominal Sections," as published in the *Medical Press and Circular*, are included the removal of the uterine appendages for myoma in 99 instances, with 7 deaths; hysterectomy in 54 cases, with 19 deaths; and one enucleation of a myoma, which proved fatal. Thus we have in all 124 completed abdominal operations bearing immediately on our present subject. From the same statistics it may be gathered that Mr. Tait has, moreover, had no less than 30 incomplete operations of this kind, 17 of which were in cases of uterine, or unspecified but non-ovarian tumours, which, after the opening of the abdominal cavity, further procedure had to be abandoned. Of these incompleting operations, Mr. Lawson Tait thinks that he "may speak with a certain amount of satisfaction," though from what he derives this contentment I am at a loss to understand, as his mortality in them was 50 per cent. "This mortality," he observes, "is of course heavy, and the results in the great majority of those who survived the operation were very unsatisfactory, though in some the disease has been arrested apparently for an indefinite time. I have no doubt now that in many of those cases I might have finished the operation, in fact I know I could, but I always had a horror of a patient dying on the operating-table, and from that distressing incident I have hitherto

been entirely free. I now think that it would have been better even to have had such a disaster, and to have finished a large number of these operations."

The journal from which I have just quoted contains other evidence of the spreading *cacoethes operandi* prevalent among abdominal sectionists. Thus Dr. Savage, in reporting upwards of a hundred cases of abdominal section undertaken within a year, boasts that he performs this operation in every case which he has "the opportunity of operating on," without "the slightest attempt at the selection of cases, and as choosing the most suitable and rejecting those which did not seem to promise to be successful." Nor does he hesitate to admit that, had there been such selection of cases, he would have had fewer deaths of patients on whom he "operated with the idea of giving them the slight chance of life the operation afforded, knowing well beforehand how slight that chance was."

Dr. Keith has recently recorded 38 cases of hysterectomy with only 3 deaths. In the *American Journal of Obstetrics* Dr. Bigelow has, with great research, collected from all available sources 359 similar operations, of which 227 resulted successfully, whilst 132 patients died. With regard to this admitted mortality, greater than one in every three operated on, we may well ask ourselves the question, which was suggested to Dr. Keith by his own more successful practice, viz., does a mortality of 8 per cent. justify an operation for a disease that, as a rule, has only a limited active life, that torments simply, and that only for a time, though of itself it rarely kills? The mortality of an ordinary uterine fibroid, if left alone, is nothing approaching a death-rate of 8 per cent. Most of the cases on which I have operated were known to me for years before; only the extreme cases were done; in nearly all the lives were useless, and the risk of operation was clearly understood. Considering the nature of the cases, it seems to me that these operations were perhaps justifiable; and, if these were barely justifiable, what can be said of those ghastly lists of hysterectomy where the mortality is one death in every two, one death in every three, or even one death in every five?

*Myotomy.*—According to Professor Schroeder, any uterine fibro-myoma, however extensive or wherever situated, may be removed by laparotomy or partial hysterectomy with the aid of the elastic ligature. The appalling mortality resulting from this operation should, however, I think, sufficiently prevent its repetition by other surgeons. Of those on whom Schroeder thus operated he lost in his first series of cases 30 per cent., and in his second series 22 per cent. of his patients.

*Oöphorectomy.*—The removal of the uterine appendages, as originally suggested by Blundell, and reintroduced into modern practice by Dr. Batty, of Georgia, whose name, as well as those of Dr. Goodell, of Philadelphia, Dr. Banker, Mr. Tait, and Mr. Knowsley Thornton, is now identified with this operation, has been largely employed within the past few years for arresting the development of fibromata, and for the prevention of uterine hæmorrhage consequent on their existence.

Before we can accept oöphorectomy as the panacea that it is claimed to be for uterine fibromata, it seems to me that further proof is needed that it is generally necessary, or feasible in such cases. It would certainly be desirable to formulate, more distinctly than has been yet done, the cases of fibro-myomata in which oöphorectomy may be resorted to with a fair prospect of benefit, and to point out those in which no reasonable anticipation of success can be held out from its performance. In the first category should be placed all actively increasing fibromata not removable per vias naturales, and more especially those occurring in young patients in whom the prospect of reaching the period when any arrest of the tumour by the natural menopause might be hoped for is remote, and who, if they survive till then, are meanwhile necessarily condemned to lives of useless suffering. Under these circumstances there can be little question of the propriety of attempting by oöphorectomy to anticipate

the distant menopause in any case in which this is feasible. But the removal of the ovaries merely for the arrest of hæmorrhage consequent on fibromata appears to me unjustifiable until other and safer methods of checking metrorrhagia have been fully and unsuccessfully employed. And I am convinced by experience that if we try these fairly we shall seldom find it impossible to arrest effectually and safely any uterine hæmorrhage thus caused without oöphorectomy. Secondly, I cannot think this operation generally advisable in the case of quiescent fibroids largely occupying the abdominal cavity in older patients. In such cases the removal of the uterine appendages is generally not merely difficult and hazardous, but even quite impossible in the instances in which, if practicable, it might be most useful. Thus in any large subperitoneal or interstitial fibroid lifting the uterus far above the pelvic cavity, and binding it to the adjoining parts by consequent inflammatory intra-peritoneal adhesions, it will be found utterly impossible to reach the ovaries by any abdominal section until the uterus, by which they are overlaid and concealed, is first detached from these adhesions and turned out of the abdominal cavity. In such a case, and it is no ideal one, having subjected our patient to all the risks of such an operation, are we to dissect out the uterine appendages and then replace the uterus and tumour *in situ*? or, in the words of an eminent American gynecologist, Dr. Drysdell, of New York, would it not "be better practice to leave the uterine appendages untouched and remove the tumour itself?"

The removal of the uterus or of its appendages must be regarded as capital operations. And though these are now apparently approached by some surgeons as a matter of routine practice, and with much the same lightness of heart as was manifested by the French Minister when embarking on the Franco-Prussian war, I confess I cannot share this view. In my student days I was taught that capital operations were justified only as means of saving life or relieving suffering otherwise hopeless. It would now, however, appear that the gravest operations may be resorted to in every case in which the opportunity presents itself. For my own part, I am unable to accept this doctrine, and am still old-fashioned enough to believe that no operation of such gravity as that under consideration should be undertaken save as a matter of necessity, and with a reasonable prospect of a successful result.

(To be continued.)

## THE NATURE AND TREATMENT OF GOUT.

By Dr. W. EBSTEIN,

Professor of Medicine and Director of the Medical Clinic at the University of Göttingen.

Non ingendum, aut excogitandum, sed invenendum quid Natura faciat aut ferat.—Bacon

(Continued from page 514, June 10th.)

### CHAPTER IV.

*The Action of Uric Acid and its Compounds, as well as of some Allied Chemical Substances on Animal Tissues and Organs.*

To the facts adduced in the former chapter in favour of the poisonous qualities of the urates, and of the varied degrees of resistance to the poison of the various tissues and organs, further, more extended and complementary proofs are here added. Amongst others for instance, by the introduction of chemically pure uric acid and its soda compounds into the tissue of the cornea of rabbits, infiltrations were invariably produced. Experiments with urea, xanthin, guanin, kreatin, kreatinine, and hippuric acids ran their course as free from reaction as the control experiments made with a 5 per cent. solution of phosphate of soda.

That a causal relationship exists between the necrosing and necrotic processes, as well as the reactive inflammation associated with them, as we have learned to recognise them as typical processes in arthritis urtica

of the human subject, and as the effect of experiments on animals, on the one side, and the regular accompaniment of gouty necrosis of tissue and the deposition of crystalline urates on the other, is *a priori* extremely probable.

I have already brought forward my views and the wherefore of them, that the gouty poison first permeates the tissues in a fluid form, damaging them more or less as the conditions present are more or less favourable, and that when the injury has reached the highest point, and not till then, the uric acid compounds, which frequently form the sole constituents of gouty deposit, crystallise out in the necrosed tissues.

I have also already ventured the supposition that uric acid plays the greatest part in the occurrence of disturbances of nutrition in the tissues and organs, that it alone can produce them, and I have there made known my desire to bring forward proofs of this. This will now be the main object of the following inquiries.

As regards the disturbances of nutrition in the gouty organism, individual observers, such as Charcot, have already noted the disposition to sphacelus. In the following chapter I shall have the opportunity of more closely considering these serious eventualities that come and go in the course of gout, and which have not escaped the older observers. With the matters interesting us at the moment, these have absolutely nothing to do. Of the necrosing and necrosed patches in the organs afflicted with gout, in the sense in which they have been treated in these pages, there has been, as far as my knowledge of the literature of the subject reaches, generally speaking, nothing hitherto said.

As regards the other form of disturbance of nutrition in gout, the inflammations, it is an experience as old as the history of the disease that this remarkable affection is associated with inflammation, and since it has become known, through Wollaston, that the tophi arthritici of the joint consist of uric acid salts, the conception has grown with time that these inflammatory processes develop in the neighbourhood of the uratic deposits. But whilst I attempt to fit these necrosing and necrotic processes into the pathology of gout as something general, as a regular occurrence in the various organs affected with gout, I will here at once remark that I consider all these things: gouty inflammations, necrosing and necrosed processes as closely allied one to another, inasmuch as they originate in a common soil and are caused by one and the same *nava*. But gangrene is often simply an outcome of the inflammation, and arises when, in consequence of the the *noxæ* in question, the nutrition of the injured tissues is completely interrupted.

If uric acid be looked upon as the foundation of all these disturbances of nutrition we must make the attempt to prove it, for which purpose experiments on animals offer a favourable field. It is a matter of wonder to me, that in our times, rich in experiment, this has not been done. It appears as if the matter were held to be too self-evident although controversy has not been wanting even here.

Garrod finds it quite natural that urates as foreign bodies set up an ordinary inflammation. Rindfleisch says the infiltration of uric acid is plainly an important mechanical-chemical irritant to the parts affected, and Cornil and Ranvier write, in the 2nd edition of the well-known "Manuel D'Histologie Pathologique," "Les cartilages, sous l'influence de l'irritation déterminée par la présence de l'urate de soude subissent des modifications, qui doivent être considérées comme de nature inflammatoire." They mean by this the processes of growth in gouty cartilage of which we spoke in the first chapter (1884, vol. ii., p. 520). For me it has been a thing to be questioned that these investigators have drawn attention to those appearances that are due to the irritating action of the urates that make their appearance in the parts surrounding them only, but not to the part that suffers the most injury from the deposits.

After Braun had already explained that excess of uric acid had no very deleterious action for the organism in

general, making reference on the occasion to the experiments of Neubauer, in which rabbits that were fed with 12 gm. daily were apparently quite well; Cantani also has made known his opinion in opposition to that of the above-mentioned investigators against the poisonous action of uric acid. He says, "Excess of uric acid in the blood (actual urate of soda) does not indicate for us the *materia peccans* of gouty irritation, or that which irritates the joints. Neither is it the cause of the local symptoms nor the basis of the local deposition of soda." Up to the present none of these observers have produced proof of the accuracy of his views, neither Cantani for his attitude against the opinion that uric acid has an irritant action, nor the others in favour of it. The poisonous action of uric acid became still more problematical as still other voices were met with in literature more or less favourable to Cantani's ideas. Bartels assumed at once that an increased excretion of uric acid was, *per se*, without injurious consequences to the organism affected. He considered that the excretion of uric acid could only produce injurious consequences by the formation of concretions from combination with the salts in the urinary passages. Heidenhain injected sufficiently concentrated solutions of urate of soda into the jugular veins of rabbits, and found that these were mostly deposited freely in all parts of the urinary tubules in the form of finely granular masses, sometimes pale and sometimes darkly coloured. In the cells themselves, which had without doubt excreted the salt, for the Malpighian capsules were completely free from urates, Heidenhain neither discovered any changes, nor is anomalous condition of cells to be noticed in the accurately drawn illustrations of the changes said to have taken place. Some years ago I caused Dr. Damsch, first assistant at my clinic, to repeat Heidenhain's experiments with regard to the influence of uric acid on the secreting parenchyma of the kidney. These results have not been published; Herr Damsch has, at my request, shortly grouped them together as follows:—If weakly alkaline solutions of urate of soda are injected into the jugular vein of rabbits it is found fifteen to twenty minutes after the injection partly in the kidneys, and indeed visible to the naked eye in direct light as most delicate white streaks parallel to the course of the urinary tubules, especially in the medullary substance, and partly in the cortical substance, in part in the tubuli recti, and in part in the tubuli contorti.

By microscopical examination the white streaks are seen to consist mainly of amorphous, crumbly masses, looking black in direct light, and lying within the canals. A portion of these streaks is arranged in rows of spherical forms, more or less filling up the lumen of the canals, having a central nucleus, with slight radial markings and strongly refracting light. The glomeruli are always free from this excretion. The epithelial lining of the tubules appears flattened at the place where the cylindrical formations lie, the lumen for the tubules is occasionally dilated, even above the occluding masses. The addition of weak alkaline solutions dissolves these concretions, and after the addition of acids typical forms of uric acid crystals make their appearance in the shape of rhombic plates. If the action of the added alkali is observed under the microscope one becomes convinced that in the situation of the sphaero-crystals *the cellular elements remain with distinct membrane with nucleus and nucleolus*. In the situation of the cylindrical formations, composed of amorphous masses, one finds after solution of the urates a delicate granular substance in which regular round nuclei are imbedded, closely pressed together, and only individual cells are seen to be retained.

If the deposits are dissolved by maceration in water of 30-35 deg. C., and then coloured with Bismarck brown, the cylindrical formations come out distinctly from the intense colouration of their nuclei. These nuclei are smaller than the nuclei of the kidney epithelium and are similar in size and appearance to white blood cor-

puscles. In isolated spots between the epithelial layers of the urinary tubules exactly analogous strongly tinged nuclei are seen (white blood corpuscles?).

These experiments teach us that, independent of the excretion of the uric acid compounds administered to rabbits by injection into the jugular vein, by the epithelium of the kidneys, as has been taught by Heidenhain, certain changes take place in the kidneys which are to be looked upon as co-effects of these injections. The uric acid compounds, excreted into the urinary tubules, which, as Meissner has already accurately described, in part completely resemble the urea granules of birds, at one time incrustate a well characterised cell, at another as apparently amorphous masses, a finely granular protoplasmic substance nuclei. In any case it results in so much that these experiments produce changes in the parenchyma of the kidneys of rabbits which stand in a causal relationship to the incorporation of alkaline uric acid solutions. These changes are reparable, for in the case of animals that were killed fourteen days after the experiment residua of them could no longer be traced in the structure of the kidney.

As regards my own experiments on the action of uric acid on the animal organs and tissues which, I will now briefly sketch. Those experiences first of all which the experiments discussed in the previous chapter yielded, were extremely favourable for the conception—1. That uric acid is a substance exceedingly harmful to the nutrition of the tissues of the animals experimented on; and 2. That all organs do not re-act equally readily to uric acid, *i.e.*, are equally injured by it. The proofs of the correctness of these views are produced without difficulty. Notwithstanding uric acid was always present in the kidneys of fowls, the ureters of which had been ligatured, and it may be said, in large quantities, necrosed patches with acicular deposit could not be demonstrated in them, although they were proved to be present most distinctly in the liver, and still more extensively in the heart. I cannot, indeed, give a more plausible and unobjectionable explanation of this than that the kidneys of fowls offer greater resistance to the action of uric acid salts than the before mentioned organs.

The experiment with chromic acid salts showed that the kidney substance also loses its power of resistance as soon as the subcutaneous administration of this poison has seriously damaged its nutrition. But one could still raise the objection against all these experiments and their significance that if, as is proved in birds, uric acid forms the principal nitrogenous excretion, yet other constituents are present in the urine that injure the nutrition of the tissues. It could be said, moreover, that in the organism of the bird, whether injured by ligature of the ureters or by the injection of chromic acid salts, still other pathological conditions might be in action, giving rise to inflammatory and necrosing processes.

A method of check was therefore necessary. One had to ascertain whether chemically pure uric acid and its combinations with soda, as far as these relate to the subject, possessed toxic properties as regarded animal tissues.

(To be continued.)

THE French Association for the Advancement of Science will meet at Grenoble, August 13th, 1885, under the presidency of Prof. Verneuil.

A SERIOUS epidemic of whooping-cough has run through the islands of the Fiji group. The malady has carried off all the very young native children, and left a decrease in the population of 3,000. A few years ago 30,000 persons in Fiji died from an epidemic of measles.

ON

### HERNIA AND ITS RADICAL CURE.

Delivered at the Royal College of Surgeons of England.

By JOHN WOOD, F.R.S., F.R.C.S.,

Hunterian Professor of Surgery and Pathology ;  
Senior Surgeon to King's College Hospital, and Professor of Clinical  
Surgery in King's College.

#### LECTURE III.—(Concluded.)

##### Operation for the Radical Cure of Umbilical Hernia.—

As a rule, a congenital umbilical hernia, more even than other varieties, has a strong tendency to get well by the progressive contraction of the ring-like cicatrix around. In this it follows the law of all circular cicatrices, which, unless prevented by other conditions, tend to contract towards the centre, and close up the aperture. Time should, therefore, in all cases, be allowed for this beneficent action of the *medicatrix nature* to exert its influence, favoured, as far as possible, by properly fitting pad and belt. But in some, either from early weakness of constitution, hereditary predisposition, frequent crying, or the neglect of proper support, the rupture remains uncured up to the adult period, or becomes so large as to be dangerous and unsightly. This constitutes a serious danger in both sexes: in the male, from the disability and weakness thereby ensuing; and in the female, from the liability to pregnancy.

In only two cases have I thought it advisable to interfere by operation for the cure of umbilical hernia in adult males. One was a finely grown young man, *æt.* 22, with a protrusion of the size of a small apple. He much wished to serve in the army, but was refused admission by the medical examiners. He was operated on June 16th, 1883, made a good recovery, had no unpleasant symptoms at all, and was finally admitted into the service, where he still remains cured. The other case was about the size of a walnut, in a lad *æt.* 14, who had been rejected by the medical examiners, for the navy. The cure was as perfect as in the last case, and no symptoms worth mentioning occurred.

In both cases the operation was done with wire, in the following manner. A small semicircular needle, with a handle and the eye near the point, and sharp enough to pierce easily the very tough and resisting cicatricial tissue around the neck of the sac, with copper wire silvered, and rather thinner and more flexible than that used for inguinal hernia, were the only instruments used in the operation. The sac was first pinched up with the thumb and fingers, and carefully emptied of its contents. It was then invaginated upon the forefinger, which was placed under the edge of the hernial opening on one side. The point of the needle was then made to transfix the tendinous margin about half an inch from the edge. The point of the needle, on raising and before perforating the skin, was carried round half a quadrant of the circular opening, and made to emerge at the upper pole of the vertical diameter. The bent end of the wire was then hooked on, and drawn back with the needle. The same manœuvre was then gone through on the opposite side, the upper end of the wire hooked on, and drawn through. The invaginating forefinger was then carried down to the lower pole of the vertical diameter, the needle passed through from behind, and then turned under the skin, so as to be made to emerge where the wire came out through the lateral puncture. The wire was again hooked on, and drawn down, a loop being left so as to emerge at each of the punctures. The same manœuvre being accomplished at the opposite side, the ends of the wire were left emerging at the lowest puncture, while a loop of wire was found at all the other punctures. The ends of the wire and the upper loop were then drawn upon until the lateral loops sank under the skin. The invaginated skin

and sac were drawn out of the aperture by traction with a pair of hooked forceps. Then, by twisting down into the punctures the upper loop and the ends of the wire below, the sides of the hernial opening were drawn powerfully together in a vertical line coinciding with the *linea alba*.

The application of tendon may be accomplished in the same manner, the ends of the ligature being tied firmly below at the lowest puncture, while the loops are all sunk into the other punctures, so as to disappear in the tissues. The method of application of the constricting ligature was, in fact, almost exactly the same as the subcutaneous ligature for *nævus*, which I have used for many years. The wire was left in for a fortnight; much thickening ensued along its track. It was finally withdrawn by untwisting the upper loop and lower ends, cutting off the latter short, and drawing upwards the former. The wire, on being straightened by stretching, came out easily.

If the rupture be a large one, it would be better to keep all the loops, the lateral ones as well as the upper ones, and twist them all down into their respective punctures. The prepared thick tendon-ligature may be used in this operation, instead of wire. It is durable enough, if properly prepared, to endure until it becomes organised, and does not require removal. After the operation, the sac of the hernia projects as a vertical ridge, which can afterwards be removed, if desirable, with a pair of scissors, when the cavity is closed at the neck. A pad of gauze, placed vertically on each side, with another thick one over them, covered with oilskin, and held on by a broad body-bandage, is all the dressing required.

In three other uncontrollable cases in children, I have operated without any serious symptoms. One was by the use of the angular pins locked together. The result in this case was not satisfactory; the rupture returned. The others were operated on by the use of the thinner wire; they were completely successful. No death, or indeed any serious symptom, ensued. The hernial opening into the peritoneal cavity was in each case closed by adhesive effusion, and the wounds scarcely even suppurred. But, in the unsuccessful case referred to, the adhesions were not strong enough to prevent a return of the rupture.

#### REVIEW OF THE VARIOUS METHODS OF ATTEMPTING A RADICAL CURE OF HERNIA.

I can only briefly allude to the numerous fellow-workers who have followed this line of surgical improvement. Scarcely any subject in the whole department of surgery has been more discussed or more written about. Not any has been more soiled by the practices of mountebanks and charlatans from the earliest dawn of the history of medicine.

The want of permanent success has been almost universal, and the danger to life of many too often demonstrated. Of the ancient methods many owed their fame to extreme ignorance on the one hand and impudent charlatanry on the other. Plasters and ointments of elecampane, caustics and the hot iron, and especially the application of oil of vitriol, brought fame and money to an impudent quack.

Excision of the sac and its covering, and in many cases the testicle also, was practised by Celsus. Galen and Paulus Egineta ligatured the sac at the superficial ring, and tied up also the cord and skin. Centuries after their time this was practised by Continental quacks, as mentioned by Dionis and Scattetus. Then was introduced the milder and more scientific proceeding of opening the sac freely, and stitching its edges close. This was called the royal stitch, because it qualified the king's lieges for military service. The punctum aureum, as described by Ambrose Paré, consisted of passing a golden or leaden wire behind both sac and cord, at the superficial ring, and twisting it down tight enough to close the hernial sac, without stopping the circulation through the testicle. In more modern times Schmucker and Langenbeck ex-

posed the sac by a free incision at the superficial ring, and ligaturing it without enclosing the cord. The fatality of this method (3 in 10 cases), and the failure of most attempts to cure in the hands of such men as Acrel, Armont, and Petit in France, and Abernethy and Sharp in this country, led to the general professional opinion of the uselessness of such operations to produce a cure, and to their actual condemnation as very dangerous to life. The efforts of surgeons then turned in the direction of truss pressure as a means of radical cure. Richter employed a strong and tight truss, with a hard pad of wood, and this method was employed by L'Estrange, of Dublin, who has been followed by many Irish and American surgeons. The injurious pressure upon the spermatic cord, as it seems to me from the shape of the pad employed, has been marked in some cases I have seen and heard of. The pain and suffering inflicted during the lengthened period necessary for a cure, and the want of skill and care of the patient in adjusting the pressure, and the difficulty and expense of a continual supply of new trusses combined to prevent a greater success than 10 or 15 per cent. of uncertain cures by this plan. But undoubtedly cases of cure by a skilful and prolonged use of an efficient truss have occurred to myself and many other surgeons. In children's cases especially it is much more frequently effected, and might be much more common if nurses and parents were as skilled as surgeons and instrument makers in adjusting them. But too often, especially in hospital practices, the attempt to cure by this method is hopeless, and the ruptures, when brought for radical cure, are large, uncontrollable, and difficult, requiring sometimes two or even three operations.

A class of operations dealing with the interior of the sac by injection of irritants like iodine and tinct. cantharides was practised unsuccessfully, and sometimes fatally, by Pelpeau and Paucoast. Another dealing with the sac by introducing solid substances, such as threads of sponge, or goldbeater's skin, with the same object, was practised with equally bad results by Schuh, Belmas, and Riggs. The method of invagination of the skin of the scrotum into the canal, and endeavouring to plug up the rings permanently, was then brought into vogue by Signoroni and Gerdy. This plan was followed by another, namely, the use of a hard wooden plug, forced along the canal, originating in Würtzer, and practised by Rothmund, Sigmund, and Spencer Wells.

In all these methods it was found that after a greater or less period of time the plug, at first apparently satisfactory, gradually made its way, pushed by the recurring hernia, down into the scrotum. In many excessive supuration brought on burrowing of pus towards the abdomen, and fatal results. The apparent cures were in a great majority of cases temporary and illusory, and the operation fell into discredit. A revival of the injection method not into, but around the neck of the sac, using astringents such as solution of oak bark, has been practised in America by Heaton, and followed by Warren and Bull.

Since the publication of my treatise on rupture in 1863, many fresh methods of proceeding, many modifications of the foregoing, founded upon plans of operating, have been originated. Mr. Spanton has invented a new instrument for uniting by adhesion the pillars of the ring. It is shaped like a corkscrew, and is introduced from the groin above downwards into the scrotum, guided by the forefinger, passed through a scrotal incision into the canal. It is removed after a week or fortnight, according to the action set up. Mr. Fitzgerald, of Melbourne, Australia, laces up the pillars of the superficial ring with a continuous gold wire suture, which he leaves in the tissues in the hope that it may permanently fulfil its functions. Professor Duwell, of Texas, sews subcutaneously the pillars of the ring with silver wire, and claims to have done 100 cases with 60 permanent cures.

It will be observed that, in all of this class of operations, the anterior wall of the inguinal canal and its superficial ring are the only parts really affected by the opera-

tion. The hinder wall and the deep ring and neck of the sac are unaffected. The result is that sooner or later the hernia makes its way behind the adhesions or the permanent wire suture, separating the former, and by constant pressure causing the latter to cut its way slowly through the tissues and become useless. In the case of the latter plan, also, there is the manifest probability of a truss being inapplicable if the hernia returns, or a weakness or bulge remains, requiring another operation for the removal of the wires within a few months. The same result will undoubtedly occur if the operation which goes by my name is imperfectly done, and the pillars of the superficial ring only are sutured. A misapprehension which may easily arise from a want of familiar and practical knowledge of anatomy has led to the application of my name to operations in which all my precautions were neglected; and also to the employment of a part of my operation only as a basis for a new method. The result has been, in many instances, a want of success, for which the operator, and not the operation, is really responsible.

Reasons somewhat like the foregoing have led to what is called the open method, or the method by dissection for the radical cure of hernia. It will be well to state here that, with the protection of the spray and the careful use of antiseptic dressings, I by no means object to, but have often employed, this method of operating. But the real factors in the production of hernia should be properly and securely dealt with. An operation which has been practised by men of ability and professional position cannot be lightly considered by anyone. As present workers in this field of surgery I may mention the names of Professors Sir J. Lister; Annandale, of Edinburgh; and Stokes, of Dublin; Sir W. MacCormac; Macleod and Buchanan, of Glasgow; Mitchell Banks, of Liverpool; and Charles Steele, of Bristol, the first, I believe, who operated for the radical cure of hernia with all the Listerian precautions.

Professor Annandale, of Edinburgh, opens the canal, ties the neck of the sac, and removes it bodily, and then stitches together the margins of the opening.

In the *Edinburgh Medical Journal* for December, 1880, he published a case of strangulated crural hernia, operated on in January, 1872, in which he tied the neck of the sac with catgut and removed it with some adherent omentum. In a case of irreducible crural hernia, operated on in January, 1880, he stitched the margins of the crural ring to the stump of the sac in addition. Professor Stokes, of Dublin, opens the sac freely, stitches up the neck, and then, without removing the sac, draws together the canal and pillars of the ring by chromicised catgut, carbolised silk, or silver wire. He considers the removal of the sac to be a risky and unsurgical proceeding. Mr. Mitchell Banks, of Liverpool, opens the canal freely, ligatures the neck of the sac, and divides it, detaches the fundus, and removes it, and then sutures up with catgut the pillars of the ring.

Mr. Alexander, of Liverpool, opens the canal by dissection, ligatures the neck of the sac with catgut, making a point of tying it so that it shall be flush with the peritoneum internally, so as to leave no digital depression. He then divides the neck of the sac below the ligature, and leaves it in the wound, without suturing the pillars of the ring. In one of the two cases of crural hernia operated on by him in June, 1880, and reported in the *Liverpool Medico-Chirurgical Journal*, the fundus of the sac afterwards sloughed out. Sir William MacCormac has followed this plan, I believe, in a good number of cases. Professor Buchanan, of Glasgow, in cases of congenital hernia, cuts down to the sac, slits it up longitudinally on each side of the cord, then divides the front part horizontally, rolls up the upper half, and with it plugs the deep ring, turning down the lower half to complete the "tunica vaginalis" above.

Many of these surgeons appear to take little pains to close up the inguinal canal as distinguished from the superficial ring. At the deep ring some close the neck of the sac, without closing the margins of the fascia that

form the ring proper. In an irreducible hernia it is of course necessary to open up the sac freely, and in many cases the inguinal canal also, in order to remove the sac entire. I accomplish this, if found necessary, by extending my usually limited incision upwards from the scrotum. The entire removal of the sac is always a tedious, severe, and often a difficult operation, if due care is taken to preserve intact the spermatic cord. It must be accomplished by much dragging and tearing and separating a great number of vessels. The spermatic cord is sometimes found spread out, and its constituents separated widely apart. In two cases of irreducible direct inguinal hernia I found it placed in front of, instead of behind, the sac—the vas deferens towards the inner, and the spermatic vessels to the outer side. In other large cases I have found the vas deferens projecting before it into the interior of the wall of the sac, with a sort of mesentery thrown around it. Much care is required in dealing with a large sac for its entire removal, and a good deal of extravasation of blood into the penis and scrotum follows in many cases—with, often, retention of urine. Banks states that it requires a good deal of "mauling," while Stokes considers the process as "unsurgical," if not "repulsive and barbarous." It may certainly be considered as a most difficult and prolonged operation, and the increased mortality which follows it shows that its effects on the system are serious. It is only very weighty reasons which would justify its performance.

With respect to the supposed advantages of the open method, enabling the surgeon to see the parts he operates on, I have myself found that, after the first cut and the application of the sponge, the parts become so bleared with blood, that I was obliged to rely mainly upon the aid of the sense of touch before I ventured to pass a needle through Poupart's ligament, the conjoined tendon, or the pillars of the ring. My experience is that this operation can be all done, and has been very frequently done by me, when the sac to be removed is not very large, through a scrotal incision two inches long reaching up to the superficial ring. The mobility and elasticity of the integuments is such that the aperture thus made can be drawn up so as to lie over the hernial opening, which is itself dilated and large enough to permit the sac to be followed, drawn out, detached, tied, and divided close to the deep ring, without any important division of the intercolumnar fascia, which necessarily weakens the abdominal wall.

A fallacy which some operators seem to entertain is that by stitching the pillars of the ring only the canal is also closed. The layers formed by the walls of the inguinal canal and the spermatic groove above Poupart's ligament, in fact, remain as loosely connected with each other, when the parts are well healed, as they did before the operation. They are movable upon each other, and slide and give way before the soft pressure of the sac to form another hernia. Abundant material for a fresh sac is found in the peritoneum forming the false ligaments of the bladder. The plans for simply tying the neck of the sac, and either cutting it off or leaving it and the sides of the canal to heal up as they lie, are simply resuscitations of the older mediæval plans, about which the late Sir William Lawrence argued "that it was futile to close up or cut off the neck of the sac, while the openings in the abdominal wall remained to admit a fresh sac, which the peritoneum was apt and ready to furnish."

#### CONCLUSION.

It appears indubitable, from the results of the last twenty or more years' experience of the radical cure of hernia, that the position of those surgical writers who have maintained that the radical cure should not be attempted, except in the severest cases, is untenable. The operation has given as great relief and exemption from the minor troubles and worry which make life miserable as any operation associated with prolapse, such as hæmorrhoids, and is even more safe. It is certainly quite as much called for, on the score of relief from pain

and inconvenience, as most other abdominal operations. Though it may not, like ovariectomy, remove the certainty of a speedy death, and may, like colotomy, be called an operation of convenience or expediency, it often relieves suffering as severe as that for which colotomy is performed, and is attended by far happier results.

The justification of the operation being admitted, it remains to consider what cases are most appropriate for it, and which of the many we have passed in review is most proper and applicable for the cases chosen. The rules I have observed in my own cases have been as follows. The subcutaneous plan has been adopted.

1. In cases of children above 5 years old, in whom trusses are useless or unavailable because of neglect, violent coughing and crying, sore groins, rapid increase in the size of the hernia, and interference with micturition.

2. In cases of young adults, or boys under 14, whose prospects in life as candidates for the naval, military, or engineering professions, or for colonising, are seriously impaired by the hernial condition. Such persons may be far from surgical assistance when the exigencies of duty or occupation may produce strangulation, or the breakage of a truss may leave them defenceless; they are subject, also, to increased life-assurance rates, from which the operation, when successful, relieves them; in able-bodied working men generally, whose various laborious employments may place them continually in danger of strangulation, and whose strength and usefulness are impaired by the hernia. The extent of the necessity for a radical cure of rupture, and the patriotic and social motives which demand it, are clearly made manifest by the various estimates of the number of recruits and conscripts rejected for this complaint. Malgaigne states that 1 in every 13 Frenchmen is ruptured; Arnaud, 1 in every 8. During the civil war in the United States, 38,132 were rejected in two years. In this country it is said that 1 in every 20 males is ruptured. The bodily ailments and mental worry which this condition and its consequences entail upon this large number of human beings make up a very impressive total of suffering. And the mortality from it must be also considered. In 1879, according to the Registrar-General's reports, as given by Mr. Spanton, no less than 1,119 deaths occurred from hernia, of which 23.5 per cent. had undergone operation for strangulation, &c. The average rate of mortality of the operation of kelotomy in 11 large hospitals is given by the same author as 41.8 per cent.; and the proportion of the mortality from hernia increases with age to a marked degree. The importance of a permanent cure effected during youth for so large and useful a class as this, when thus viewed, rises to the point of a national demand.

3. In reducible cases, where the sac is thick and indurated from truss-pressure, or where the omentum is continually slipping down under the truss, showing thereby that it is abnormally elongated, I open the sac, tie the vessels of the omentum separately, and remove it below the ligatures; tie up the neck of the sac flush with the peritoneum at the deep hernial opening, and apply wire or tendon-ligature to the canal and rings. When, by any cause, the first operation fails in effecting a satisfactory cure also, I open the sac, inspect its interior to discover any special cause for the failure, tie and remove the sac, and lace up the canal and rings with especial care and security.

4. In all favourable cases of strangulated hernia, both inguinal and crural, the coverings and front wall of the canal being necessarily divided to search for the constricting tissues, I open the sac, examine the contents, remove adhesions and doubtful portions of omentum, then tie up the neck of the sac, cut it off short, and remove it altogether (except in congenital hernia), and secure the walls of the canal and rings, as in the subcutaneous method. Of course a wrong diagnosis of the condition of the bowel or omentum, and their fitness to be returned into the abdomen or some other cause arising from the strangulation, may, in these cases, result in a

fatal issue. But I believe strongly that, if drainage is free, and skilfully arranged, no increase of risk ensues from the attempt to produce a radical cure. Quite lately I have done this in a case of *reductio en bloc* in a man who is now convalescent in the hospital.

5. Cases of irreducible hernia, and of large and unmanageable cases of reducible hernia, in patients otherwise in a good state of general health, and not above the age of 60, and in which truss pressure entirely fails to render the patient comfortable and free from danger, seem to me to justify and to require operation, if the patient wishes for the benefits which he may reasonably expect from a carefully conducted operation, under strict antiseptic methods. In all cases he should have the chances fairly laid before him in a way that he can understand, and then have the option without bias or persuasion.

In these cases, as in the last class, the operation necessarily assumes more or less of the character of an operation. The sac is freely opened, and is tied and removed, but the suturing of the canal and rings is effected as in the subcutaneous method.

In bringing my allotted task to a conclusion, I am deeply conscious that a very considerable part of these lectures has gone over ground which has been elementary enough to re-echo the household words of every dissecting-room and tutor's class. In extenuation, I have to plead that the subject demanded a good deal of such anatomical repetition to preserve its coherency and to make it understood.

After all my efforts I fear that there still remains much room for elucidation—and I have been led to think so because men who have arrived at considerable position in the profession have declared to me that they were unable to comprehend my method of operating until they had seen it done by me, and that it was much more simple to see and to do it than to describe it.

At the risk of being tedious to the more experienced of my hearers, I have endeavoured to be clear to those less learned and less experienced. I have some fear that there is no doubt about the first, but that I may not have succeeded in the last as fully as I could have desired. At any rate, I have done the best that was in me to ascertain the exact truth about the possibility of a permanent cure of hernia, to prove it as convincingly as I was able, and to state it as simply as I could, and as shortly and completely as the scope of these lectures has demanded.

The last part of my duty now presents itself, and that is to thank you, Mr. President and gentlemen, most sincerely for your presence and kindness during my lectures.

WOLVERHAMPTON AND STAFFORDSHIRE  
GENERAL HOSPITAL.

*A Successful Case of Ovariectomy. (a)*

(a) Read before the British Gynaecological Society, June 24th, 1885.

Under the care of Mr. VINCENT JACKSON,  
Senior Surgeon.

S. A. B., æt. 29 (the first patient admitted into the Women's Surgical Infirmary of the above institution), admitted March, 1885, married twelve years, has had six children, the eldest being 10 years of age, and the youngest ten weeks. History of menstruation and general health good. Seven months ago when pregnant considered herself larger than during previous pregnancies, but beyond this there was no other indication of the existence of a tumour until her confinement last December, shortly after which one was detected, and it was owing to its rapid growth, and the great discomfort it occasioned, that she presented herself for admission. Upon examination there was no difficulty in forming the diagnosis of the presence of a left ovarian tumour with thin walls. The evidence of the existence of adhesions was almost *nil*. Girth at umbilical line was 42 inches. An operation was recommended, and the patient willingly assented, but the performance of the same was delayed until

completion of the new department for such special operations.

On April 18th ether was administered, and ovariectomy was performed. A small quantity of fluid escaped immediately the peritoneum was incised. A thick membrane of lymph separated this membrane from the cyst wall. The introduction of the hand broke this down, and enabled the relations of the cyst to the abdominal walls and viscera to be determined. Very extensive adhesions were encountered anteriorly also on the left side, and one very tough attachment to the pelvis was left to be dealt with at a later stage. The larger viscera seemed free. A trocar was pushed into the tumour, but only a little thickish fluid flowed away, the cyst wall was so soft and thin that the slightest traction caused it to tear in more than one place, letting free a considerable quantity of gluey fluid. The right hand was thrust within the cyst, and as much of the interior as possible broken down and pressed out, and with one hand inside and the other outside the tumour was extracted. Now the broad adhesion to the left pelvic brim was ligatured and then divided. Attached to the tumour for a considerable distance was a long length of the great omentum as well as a piece of the small intestine, the latter was pulled off, and the former, after being ligatured in several places, was cut away. It measured fifteen inches by six. The pedicle was tied in two positions by strong silk, cut across and dropped into the pelvic well. The right ovary was healthy. After a complete cleansing of the peritoneal cavity, a glass drainage tube was inserted, and the abdomen closed by means of nine deep silk sutures, and the dressings having been applied, the patient was placed in bed and soon rallied, her progress to convalescence was rapid. On the fifth day the drainage tube was removed, having given exit to 17½ ounces of red serum, and on the twenty-first day she left for a convalescent home. The specimen, which weighed five pounds, was reported to be a well-marked example of a compound cystic ovarian tumour.

ACADEMY OF MEDICINE IN IRELAND.

SURGICAL SECTION.

FRIDAY, APRIL 24, 1885.

The President, Dr. E. H. BENNETT, in the chair.

### SURGERY OF THE KNEE-JOINT.

MR. J. K. BARTON said some points of interest in the surgery of the knee-joint are illustrated by the following six cases:—1st. Excision for advancing disease. 2nd. Excision for deformity. 3rd. Amputation through the joint. 4th. Removal of an enlarged bursa patella. 5th. Removal of a loose cartilage from the joint. 6th. Withdrawal of part of a sewing-needle from the joint. The patients upon whom the first three operations were performed were all present, and exhibited. The first was a sailor boy, æt. 14; the second a girl of 8; the third a girl of about twelve. The first case of excision had suffered from periostitis of the femur, but the result (now more than a year since the operation) was satisfactory, the boy walking nimbly and firmly without a stick or support of any kind. The second case was not so far advanced, but there was very firm union, allowing the child to walk well, but still with the help of crutches. The third case was one of amputation through the knee-joint, in a case in which the limb from the knee down was rendered useless by paralysis. The cartilages had been left; the stump was an excellent one. The fourth case was one of enormous enlargement of the bursa patella, of which a cast was exhibited. The operation which was undertaken for its removal consisted of the cutting of a very narrow elliptical piece of skin from the front of the tumour, and a similar piece from the front wall of the bursa, after which the contents, which were of the consistence and appearance of boiled sago, were all removed, then the sides were laid down, a drainage tube inserted at each end, and the edges united with carbolic gut suture; the dressing was by sero-sublimite (one per cent.) gauze; there was no suppuration. Two dressings sufficient to completely heal the wound. In the fifth case a loose cartilage had been found under the tendon of the ex-

tensor, easily pushed out and back again. It was removed by a free incision under spray, and the wound was dressed with the sero-sublimate gauze. The highest temperature marked was 101° on the second night after the operation, after which it speedily became normal, and the patient returned to the country quite well. The last of the series was that of a housemaid, who in kneeling on the stairs had got a needle into the knee, which, in endeavouring to extract, she broke. The pointed half was left deeply fixed below the patella and in the fibres of the ligament. A free incision was necessary to find it; it was found directed straight in towards the joint, and safely drawn out.

The relation of the cases was accompanied by comments upon the most interesting features of each.

The PRESIDENT disclaimed credit for the splint exhibited, as being on the basis of that of Watson, of Edinburgh. Although the mode of fixing it might vary, the moulding was due to Patrick Heron Watson, as well as the credit for so great a success in excisions at the knee-joint. While the author had dwelt on the necessity of the long anterior flap, and such was generally adopted, yet that flap was unsuitable in cases where disease existed on the front of the limb. About two or three years ago Hardy, of Manchester, published a paper recommending, instead of the long anterior, the oblique circular, amputation. "An opportunity occurring, in the case of a woman, *æt. fifty*, he followed the procedure suggested, with one advantage, that he was not limited in front for coverings by the disease, which was lupus. A plain-cut surface, instead of being at right angles, was sloped at 45°. The procedure was a little more difficult to carry out, but the covering was perfect. In that case he left the patella and the cartilages of the tibia in the joint without any serious consequences from death of cartilages said to result from that course.

Mr. STOKES emphasised as very important the method of dealing with cases of excision of the knee-joint after the operation. Speaking from an experience of twenty cases, he had tried different plans of treatment: (1) Placing the limb in a large box; (2) fixing the limb by means of gypsum bandages or other immovable apparatus; (3) the plan of Patrick Heron Watson, in which the principle was not a posterior but an anterior splint.

The PRESIDENT.—He has both.

Mr. STOKES, continuing, said he had also tried a modification of Watson's plan, devised by his colleague, Mr. Thomson. Instead of strong brass or iron wire, such as in the apparatus on view, a hoop-iron splint was applied both anteriorly and posteriorly, being fixed in position by means of gypsum. But after due trial he had abandoned the gypsum, adopting, however, the plan of the hoop-iron anterior and posterior splints, affixed by broad belts, and these fixed again on an inclined plane to give ample space anteriorly and posteriorly for the dressing of the wound. Quite as important as careful antiseptic dressing was the absolute fixation of the limb during the healing of the wound. But in the apparatus Dr. Barton had brought forward he did not see adequate provision for insuring that essential in the after-treatment of excision of the knee-joint. At the next meeting he hoped to exhibit an apparatus devised by himself and the late resident surgeon of the Richmond Hospital, and which, he thought, met the requirements desired better than any other he had seen, the principle of absolute fixation being fully carried out, as well as that of keeping the limb in an inclined plane—*i.e.*, the lower portion of the limb elevated with the view of preventing the tilting forward of the femur, and insuring in that position that the weight of the lower limb pressing against the femur helped to keep the parts from being displaced. In addition, he adopted the precaution of suturing the bones in the last two cases of excision of the knee. The result of one of these cases he exhibited at the last meeting but one of the Surgical Section. But in Dr. Barton's apparatus there was another objectionable feature—namely, that it fitted accurately along the posterior portion of the limb, not giving room for changing the dressing within the splint, and therefore necessitating dressing external to it. No matter how careful the dressing was carried out, accumulations would form between the splint and the integumental structure, which could not be cleaned where the splint was so closely applied, and therefore antiseptic dressing could not be carried out.

Dr. BALL considered Dr. Barton's limitation as to the utility of amputating through the knee-joint practically excluded primary amputation. He had himself two cases

of that operation. Both were railway accidents, in which the limb was crushed, and the head of the tibia splintered into the knee-joint. The usual anterior flap by Carden's method was adopted. The covering of the end of the bone was formed by the skin, which was naturally over the tubercle of the tibia, and was a portion of skin on which persons were accustomed to kneel. Those who claimed superiority for the supra-condyloid operation considered that by bringing the patella down over the cut surface of the femur this was secured. But this was not the case—it was the skin over the tubercle of the tibia that was brought down. As the result, the patients were able to bear the entire weight over the stump quite as well as after Symes' amputation. Both his patients were able to walk without a bucket leg. One of them was advanced in pregnancy, and she was well in a fortnight, while the child was the healthiest she ever had. With regard to the splint, he moulded a piece of wire in the ordinary way as a model, and then got a piece of flat steel, one-eighth of an inch thick, made into exactly the same shape, and rigid, permitting of no flexion whatever, whereas in the wire there was always an amount of spring.

Dr. HAMILTON was puzzled, from what he had heard, to determine whether there was an absolute necessity for performing the operation so high up, as the leg was in a comparatively healthy state. He would himself have hesitated before amputating through the knee-joint, and would probably have been satisfied with amputation below the knee, allowing the patient to rest upon the knee as the natural point of support. Of course Dr. Barton would give reasons for preferring the upper operation; but it was a rule in surgery to cut away as little as possible of the living limb. He had himself had an opportunity of trying almost every splint, and he was perfectly satisfied with the results obtained from Watson's splint, with a little addition. He used a back splint of exceedingly firm material, and he applied to it a very strong iron bracket, which enabled him to leave the limb perfectly undisturbed, and at the same time to renew the dressing as often as he wished. Thus the limb was kept with that perfect rigidity which, as Mr. Stokes remarked, was so important in the treatment of those cases. The splint was made of steel, and sufficiently wide to allow the dressings to be removed without disturbing fixation. He agreed with Dr. Ball that the thin wire splint did not give the desired security.

Mr. THOMSON believed that almost as many splints and modifications of them had been devised for the after-treatment of excision of the knee-joint as in fracture of the patella, and that everybody who had had some experience of a particular splint would probably modify it to suit his own wishes. He had himself used two or three, beginning with Watson's—the one in which the posterior splint was made of scored wood, and there was an anterior metal rod extending from the thigh to the foot. The posterior splint was first padded with a considerable amount of cotton wool to allow the limb to lie quietly and easily in it. Then the plaster of Paris was applied. He found after some weeks, when the limb had settled down into the splint, a great deal of looseness occurred, so that though in the early days a considerable amount of fixation had been secured, yet this was not so in two or three weeks before actual union took place. Next he tried the excellent splint devised by Dr. Hays, of the Mater Misericordiarum Hospital, but it did not admit of getting the retaining material sufficiently close upon the limb. After that it struck him that by using hoop-iron, which was introduced in the treatment of morbus coxae by Dr. Thomas, of Liverpool, he would, provided it was of sufficient strength and thickness, obtain a splint that would answer his requirements. The hoop-iron splint had certain advantages to recommend it, being easily procurable in the country, and capable of being shaped to the limb by bending across the edge of a table, or across the knee. He used a posterior splint of plain hoop-iron, and an anterior one moulded in the same way. From the difficulty of cutting through the plaster of Paris once it was applied, he abandoned it, and now used an ordinary flannel bandage. The results from using the splint which he adopted were exceedingly good, but a wire splint a quarter of an inch thick, such as Mr. Barton's, was unequal to supporting a limb.

Dr. BARTON, in reply, concurred with Mr. Stokes that fixation of the parts was of the first importance. He used a paraffin bandage as lighter than plaster, amalgamating the lower part of the limb and the wire splint, and supporting

the splint with sand-bags or a light Liston-like splint placed along from the axilla. This was outside the dressings, and was a supplementary dressing. But to his mind the recommendation of the wire consisted in the very point which Mr. Stokes considered faulty—namely, that it was entirely inside the bandage close to, into the skin, and against the popliteal space, and the antiseptic dressings went round it. In seeking fifty every time the antiseptic dressings were changed, so far as there was a movement of the limb, they destroyed with one hand what they were endeavouring to gain with the other. But the wire remained perfectly steady, and the antiseptic dressings were changed without any movement being communicated to the limb. The wire might be too tight, but he did not think it was. With regard to Mr. Hamilton's remark, his reply justifying the operation was that there was no power over the limb below the knee-joint. The muscles acting on the tibia and fibula were paralysed, and therefore to leave what was no longer under the voluntary control of the patient would have been a mistake.

#### URARI IN THE TREATMENT OF TETANUS.

Mr. M'ARDLE read the notes of a case of acute traumatic tetanus, in which two-third grain doses of urari every fifth hour resulted in a cure, the more remarkable effects produced by the above-named doses being relaxation of the contracted muscles in from six to ten minutes after administration, very rapid and tumultuous action of the heart, cyanosis, laboured breathing, and dilatation of the pupils. Once the patient was sufficiently under the influence of urari, the evacuations from the bowels were regular. Mr. M'Arde suggested the combination of urari and pilocarpin, in the hope that the cardiac and respiratory trouble produced by the former might be prevented by the latter. He also showed that urari, to be of service, must be prevented by the latter. He also showed that urari, to be of service, must be used in large doses, and that the drug is cumulative.

The section then adjourned.

#### MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

The President, Dr. LITTLEJOHN, F.R.C.S.E., in the chair.

An ordinary meeting was held on Wednesday, July 1st, when Prof. GRAINGER STEWART exhibited several cases of clinical interest. The first was a case of

#### ABSOLUTE DEAFNESS CONSEQUENT ON A FALL ON THE PAVEMENT.

The patient was taken up unconscious, and there were evident signs of fracture of the base of the skull. Consciousness was soon recovered, but since then the patient has not heard a sound. The loss of auditory perception was not accompanied by paralysis of any other nerve. Professor Stewart inclined, therefore, to regard it as probably a case of deafness due to disturbance of the auditory centres. The other cases—a father and two sons—formed

#### A FAMILY GROUP AFFECTED WITH DISEASE OF THE SPINAL CORD.

There was no family history of nervous disease in the father's case, except that several of his children had suffered from nervous affections, while in the case of the boys, in addition to their father being thus affected, there was a history of more than one case of what seemed to have been pseudo-hypertrophic paralysis. The father had been a miner for about thirty years; the boys were at school so long as they were able. The father showed marked symptoms of primary lateral sclerosis, while both boys were evidently suffering from pseudo-hypertrophic paralysis, with possibly something resembling the father's ailment superadded.

Dr. ALLEN JAMIESON showed a case of morphea of the scalp. He also exhibited a specimen of Oleum Declani, a new oil, which seemed likely to prove of considerable service in the treatment of skin diseases.

Dr. G. HUNTER, Linlithgow, read a paper on

#### THE PLACE OF SPECIALISM IN GENERAL PRACTICE,

with reference to diseases of the eye, ear, and throat. He felt strongly that the importance of these special subjects was not sufficiently impressed on the student preparing himself for general practice, nor were satisfactory means adopted in most schools to enable him practically to become

acquainted with such diseases. He illustrated his proposition by the narration of a number of cases seen by himself in the earlier years of practice, whose puzzling nature was really due to this deficiency of preparation. Only years of practice, combined with study, would enable them to acquire that knowledge, which every man should be possessed of, in his student days. He did not plead for universalism in practice, but he maintained that every practitioner should at least know *when* to send his patient to the specialist. At present, he feared, a number of cases were allowed to suffer from want of this knowledge. In country districts, and especially for practice among the poor, it was essential that the doctor be himself ready to undertake the treatment of a large proportion of these. Dr. Hunter went fully into the subject of diseases of the eye. His opinion was that, as a rule, operations on the eyeball, and perhaps also for strabismus, and the correction of the more obscure forms of errors of refraction, should be reserved for the specialist, while the ordinary attendant should be prepared for the accurate treatment of the rest.

The PRESIDENT thanked Dr. Hunter for his most valuable and suggestive communication. He was glad that Dr. Hunter's universal sweep had limited itself at diagnosis. Otherwise the presence of a few such men in the neighbourhood of their larger cities would considerably empty the hospital wards and reduce the work of their specialists.

Professor GRAINGER STEWART congratulated Dr. Hunter on this thoughtful expression of opinion, grounded on the results of one of the largest and most successful of practices. So strongly had he felt the necessity of increased training in these lines that, in connection with the class of practice of physic, he had established a tutorial class, open to all his students, for practical instruction in the use of the ophthalmoscope and laryngoscope. The ordinary student did not want long systematic courses in these special subjects. The desideratum was short courses of practical or clinical demonstrations, where the student would become personally acquainted with the methods of treating the commoner forms of disease. Already these had been introduced in connection with some departments. He should like to see them more general.

Dr. ARGYLL ROBERTSON thought that such instruction should form part of the regular curriculum. In every European country except our own these subjects were practically compulsory. It was a pity that they should be behind their Continental brethren in the matter.

Dr. MCBRIDE was of opinion that some system such as that advocated by Professor Stewart, of short clinical courses, would best meet the wants of the case.

Mr. A. G. MILLER entered his protest against the increase of compulsory classes. He thought a number of the special subjects might be covered by the existing chairs. It might even become a question whether the present fees should not be reduced. They must consider the pecuniary resources of their students.

Dr. P. A. YOUNG felt that the want would best be met by following the example of America, and instituting post-graduate classes. While it might be unwise to lengthen their present curriculum, there were a number of men who would gladly avail themselves of such opportunity. There were several of the younger teachers and practitioners well qualified for the conduct of these courses.

#### THE BRITISH GYNÆCOLOGICAL SOCIETY.

The ordinary fortnightly meeting was held on May 27th, Dr. MEADOWS, President, in the Chair.

Mr. LAWSON TAIT showed a number of cases of pyosalpinx.

Dr. MORE MADDEN, on behalf of Dr. DUKE, of Dublin, showed a new vaginal speculum constructed so as to give more dilation than is ordinarily obtained.

Mr. MANSELL MOULLIN exhibited specimens of wood-wool and sanitary towels made of same treated with corrosive sublimate.

Mr. LAWSON TAIT then commenced the discussion on Dr. More Madden's paper on

#### SOME POINTS IN THE TREATMENT OF UTERINE FIBROMATA,

read before the Society at a previous meeting, and

which will be found at page 23. He objected most strongly to the statistics of mortality quoted, as the fatal cases occurred in the earlier part of practice before so much experience had been obtained, and now he looked upon hysterectomy as an operation with so very slight danger that it should never be refused to a patient. The disease is a decidedly fatal one, but the death of the patient is usually put down to other complications or to the exhaustion caused by the hæmorrhage. Medical treatment was in this connection a myth, and the danger incurred by injecting the tumours was probably greater than the advantage gained. Surgical treatment was so satisfactory in reasonably early cases, that under forty years of age oöphorectomy might be considered devoid of special danger, and hysterectomy a very satisfactory operation in the hands of some. Enucleation, on the contrary, had been so fatal in his practice that he would attempt no more.

Dr. BANTOCK concurred in the views expressed by Mr. Lawson Tait, and further directed attention to the pathological views of the author, which he could not at all agree with, as he believed each tumour had its special character according to the spot in which it originated. Spontaneous cure was almost as poor a hope as that of finding the philosopher's stone, as after forty years' experience he could only record one case. He objected strongly to the statement that fibromata never directly caused death. As to enucleation, except in cases of very small specimens, he regarded the operation as very dangerous.

Dr. MASON considered each operation mentioned might prove very useful in appropriate cases, and did not feel disposed to condemn enucleation so strongly as had been done, at the same time would not attempt the removal of large tumours thus.

Dr. MORE MADDEN made a short reply.

It was moved by Dr. BARNES and seconded by Dr. ROUTH, that the discussion be adjourned until June 24th.

## BRIEF NOTES FROM OUR EXCHANGES.

**THE ADMINISTRATION OF IODIDE OF POTASSIUM IN MILK.**—Dr. E. L. Keyes (*Philadelphia Medical News*) strongly recommends milk as a suitable vehicle for iodide of potassium, especially where it has to be given in large quantities, and where there is more or less intolerance of the drug on the part of the patient. Ten grains of the drug in a gill of milk (cold) make a very palatable drink, and impart only a mild, metallic taste to the fluid, which most patients find not at all disagreeable. He gives, as an example, in case of a gentleman the subject of precocious malignant syphilis (rupial in type) with a feeble stomach, who could not digest the iodides well, as they deranged his stomach, and caused disfiguring acne, a twenty-grain dose of the iodide of sodium being too much for him. This gentleman became the subject of syphilitic paralysis in the right side and aphasia. The treatment adopted was the cessation of all other foods, drinks, and medicines, and the hourly exhibition of 10 grains of the iodide of potassium in a claret glass of milk. In the first 24 hours he took 240 grains of the iodide, and nearly three quarts of milk. A laxative was the only other thing allowed. Each second day, the daily dose was increased two drachms, and after a week mercurial inunctions were also employed until the gums were rapidly touched. During his second week, his daily dose reached 3j. ss. of the iodide. Milk was his only food. His tongue cleared, the acne disappeared from his face, early in the second week he began to move his arm and leg spontaneously. He made an excellent recovery under further treatment of electricity and massage. In one month from onset of the attack he was able to leave New York, walking with the assistance of a cane, and only slight dragging of his foot; he talked as naturally as ever, and was looking well. His dose when leaving was 3x. in four doses, and this treatment was still continuing to date of publication, with the promise of a nearly, if not quite, perfect recovery.

**NEPHRECTOMY FOR ENCEPHALOID TUMOUR OF THE KIDNEY.**—M. Pean performed this operation upon a woman who insisted upon undergoing it, although advised against doing so. The method of operating was as follows (*L'Union*

*Medicale*):—"The tumour was exposed by an incision in the median line, extending from the epigastrium to the pubis. The mesentery was incised, and the numerous dilated veins treated by compression. The tumour was then found to be surrounded by a capsule, which was, to a certain extent, removable by the fingers. Before continuing the removal of the capsule further, the tumour was taken away by degrees in small portions, partially with the fingers, and partially with a spatula. This necessitated the compression of numerous arterial and venous trunks. The operation was continued till the whole mass was removed. The diseased tissue was darkish green in colour, ecchymosed in spots, and contained throughout its mass granular calcareous nodules. It was adherent, moreover, to portions of the small intestine, the mesentery, and to some of the vascular trunks, to separate it from which required great care. It was discovered that the growth had its origin in the right kidney, of which the pelvis and the ureters were in a state of fatty degeneration. The kidney and its appendages were then removed, the vessels and ureters being cut between two ligatures. The mesentery was then united by three ligatures, which were left in the abdominal cavity. The operation lasted one hour. The tumour weighed more than twelve pounds. In three weeks the woman was convalescent. A microscopical examination by M. Robin showed the tumour to be an epithelioma of the kidney.

## France

[FROM OUR OWN CORRESPONDENT.]

**ERYSIPELAS.**—At the Académie de Médecine M. Verneuil continued the discussion on erysipelas in surgical wards and the means to prevent it. He said that all surgeons recognised the necessity of combating the disease by antiseptic measures, but the methods employed were very various. Those who follow M. Trelat suture every wound, while those who follow the speaker unite rarely the wound, and M. le Fort will not use carbolic acid. M. Verneuil himself thought that antiseptic measures were not sufficient; they should be accompanied by isolation. M. Guérin observed that his dressing by cotton filters the air so that the germs cannot reach the wounds, and consequently erysipelas need not be dreaded. M. Trelat considered that the microbe of erysipelas was in general benign; when the case became grave it was the result of great quantities crowding on the wound together with other infectious germs. M. Verneuil replied by expressing the desire that special wards should be set apart for the reception of cases of erysipelas.

**HYPOGASTRIC LITHOTOMY.**—M. Terrillon communicated a case of hypogastric lithotomy to the Société de Chirurgie. After having crushed with the lithotrite a stone which lay in the *bas fond* of the bladder, M. Terrillon explored the remainder of the vesical cavity, and met with, in the upper part of the organ, a hard body. He immediately performed hypogastric lithotomy, and found five calculi encysted, which were speedily taken out, and the patient made a good cure. M. Terrillon insisted on the good results of lithotomy through the hypogastric region, in which he was supported by M. Monod.

**TREATMENT OF CHOREA.**—M. Joffroy, physician of the Hôpital des Enfants Malades, has published his manner of treatment of St. Vitus's dance, for which he claims precedence as far as results are concerned. He says, the treatment I employ in every case is, chloral given in frequent doses so as to produce almost continued sleep and the wet sheet. Already in 1879 I gave the hypnotic with the same results. To one child I administered 15 grains of chloral every quarter of an hour until sleep came on, and when the child awakened another 15 grains were given, so that sleep was

only interrupted twice in the twenty-four hours, in order to allow the patient time to eat. I continued this method during four days, but I did not see any amelioration from it. However, lately I have adopted another method, which has succeeded very well. I give the chloral three times a day regularly during a fortnight, or even six weeks, without ever seeing any ill-effects from it. Above ten years I order a drachm of chloral to be given in the day—15 grains in the morning, the same amount at noon, and *thirty* grains at night. In children from six to eight years 45 grains should not be exceeded in the day. In any case a dose to produce sleep a quarter of an hour after its administration must be given, and continued regularly until all choreic agitation ceases, and the cure complete. In the majority of cases the above treatment will suffice, but when the case is very grave the wet sheet becomes a powerful auxiliary. I order it twice a day. The water must be very cold in which the sheet is steeped, and when it is wrung moderately, it is wound round the patient tightly, and the child is rubbed vigorously from head to foot. At the end of a couple of minutes the child is covered with blankets closely and put on the bed, when reaction soon commences. After half an hour of this vapour bath the child feels a *bien-être*, and often falls to sleep.

Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Rue Hautefeuille, Paris—post free in advance, £1 3s. 6d. per annum.

SUBSCRIPTIONS FOR RUSSIA are received by Messrs. RAJCHMAN and FRENDLER, 18 Senatoren Street, Warsaw—post free, £1 5s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York by Messrs. WILLMER & ROGERS; Philadelphia, by Dr. BRINTON: post free in advance, 5½ dollars (£1 3s. 6d.) per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-Office Order.

## The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 8, 1885.

### LONDON UNIVERSITY REFORM.

On the twenty-fourth of February in the present year Convocation of the University of London was so far

roused to a sense of the reality of external dissatisfaction with the exclusive character of existing regulations as to the degree in medicine that it appointed a special committee to consider the whole question of reforming the constitution of the University, with a view to rescuing it from the oblivion into which it must certainly sink unless some steps are soon taken to preserve it from its threatened fate. This committee has now presented its report, the perusal of which is calculated to awake a feeling of despair in the breasts of not a few would-be "constitutionalist" members of the corporation; while those who regard the institution as being a "people's" convenient substitute for a real University will probably regard it as a feeble indication of changes that must inevitably follow the popular cry for reform. That it will satisfy their aspirations cannot for a moment be supposed; but possibly they will accept it for the time as an earnest of "more to follow," and in this light look on it as a harmless tinkering with necessity.

The "scheme" considers the future constitution of the University under the heads of—1. Senate; 2. Convocation; 3. Constituent Colleges; 4. Faculties; and, 5. Boards of Studies; with the Queen as visitor. It will thus be seen that a radical innovation is sanctioned by the introduction of constituent colleges into the structure of the University; and that this reform is to be something more than nominal is shown by the provision that constituent colleges shall nominate their own representatives on the various faculties of the University, while each faculty—of which there are to be four, viz., Arts, Law, Science, and Medicine—will return three members to the Senate. Thus the last-named body will have a composite and practically representative nature, consisting, in addition to the twelve members just mentioned, of six Crown nominees, six nominated by Convocation, and one each by the following bodies, if and when they respectively become "constituent colleges," viz., the Presidents of the Colleges of Physicians and Surgeons in London, the heads of University and King's Colleges, the Chairman of the Council of Legal Education, and the President of the Incorporated Law Society. Official members of the Senate are to be the Chancellor and Vice-Chancellor of the University and the Chairman of Convocation. Convocation itself remains unchanged under the new scheme.

The principal alteration conceded, however, is that relating to "Boards of Studies." Of these one will be created for each faculty, and its members elected by the faculty interested, the principal function of the board being to consult and advise on matters connected with examinations, new degrees, courses and methods of instruction, &c., &c. Moreover, as the faculty in each case will include representatives of the teaching institutions, or "constituent colleges," it is clear that the varying requirements of students and teachers will constantly exert a controlling influence over examiners and examinations; and when this shall be secured one of the worst evils of the existing system will be effectually removed.

We do not observe any provision in the scheme for doing away with that most oppressive regulation which

requires that candidates for medical degrees shall pursue the curriculum concurrently with the period of examination. As we have already shown, this is a most unjust restriction, which prevents many men from taking the London degree later in life, because of their inability or disinclination once more to go through the career of a student of medicine. The rule is obnoxious in every respect, and as it must be rescinded, provision to this end should be made in the draft scheme of reconstitution.

#### THE COLLEGE ELECTION.

THE result of the election on Thursday last at the Royal College of Surgeons of England is that Messrs. Savory, Pemberton, and Macnamara are returned as members of the Council, the number of votes obtained by each candidate having been nearly the same when "plumpers" are excluded, the figures being—Savory 141, Pemberton 128, and Macnamara 123. The "solid" votes recorded were for each, in the order named, 41, 12, and 4, thus bringing the totals to 182, 140, and 127 respectively. It is a matter of satisfaction to us that the two candidates we have especially named as prominently associated with the reform movement have been so well supported by Fellows of the College; and though the principal opponent of change in the constitution of the Council, Mr. Savory, has nominally a larger following than his two fellow Councillors, yet in connection with this result we must remember that the Association of Fellows magnanimously abstained from taking such action as would have entailed the defeat of Mr. Savory at the poll. Had the Association decided on sending forward three nominees the result can hardly be doubted; and we trust Mr. Savory appreciates aright the admirable courtesy and good feeling with which he has been treated on this occasion. It is now abundantly clear that henceforth candidates for seats in the Council will have to reckon with the reform party outside, and that a ruling influence will be exerted on all future elections by the Association of Fellows. The overpowering majorities obtained by the two candidates whom it has recommended this year is a sufficient answer to any who would dispute the popularity of the cause it has been created to advance; and it is a matter of certainty that its representatives will each year forward find admission to the Council chamber, until the time will arrive when the principles advocated by them will command an absolute majority, not only among Fellows of the College, but as well in the ruling body of it.

As an indication of the firm hold which the reform party has upon the sympathies of the general body of Fellows the recent election could not be more convincing; it is equally prophetic of the final defeat of the dogged opposition that persists in obstructing the welfare of the College by clinging to abuses that are universally recognised and condemned.

THE health of the country is now remarkably good, and the mortality low in consequence. The official returns from all the large cities show an utter absence of epidemics in any form.

### Notes on Current Topics.

#### Proposed Institution of a Medical School in Dundee.

THE teaching of medicine has not been a great success in St. Andrews. This is, doubtless, explicable on many grounds. But it has long been felt—and especially since the inauguration of the University College of Dundee—that something might be done to utilise the wealth of material to be found in the Dundee Infirmary, with its 250 beds and large out-patient department. Dundee is both a great manufacturing town—its population being estimated at over 150,000—and a shipping station of considerable importance, so that her wealth, medically speaking, is not likely to diminish, but rather to increase. Among the resident medical men—a large number of whom are Edinburgh graduates—there is the nucleus of a good teaching staff, and we believe that they themselves are not disinclined for a movement such as this. As at present constituted, even in the event of a full medical curriculum being arranged, it would be impossible for the University College to grant degrees in medicine, but, it will be remembered, the Universities (Scotland) Bill, 1885, has a clause by which St. Andrews University may affiliate colleges in other towns.

On Saturday week, after the presentation of the prizes to the successful students at the University College, Dundee, Professor Gairdner, of the University of Glasgow, delivered an address on "Medical Education." In the course of this, Prof. Gairdner compared the system of training for the medical profession now with that in vogue thirty years ago. While granting the vastly broader basis on which the medical man's training now-a-days stood, he maintained that perhaps too little attention was devoted to the consideration of those more practical questions which occupied the man's lifetime, and some of which were undoubtedly better answered by the old English system of apprenticeship. To overcome this difficulty two courses had been suggested. The one was to relegate a considerable portion of the more preliminary study in medicine to the schools, such as chemistry, physics, and biology, and include examination in these departments in their entrance tests. It was, however, doubtful whether the schools could ever adequately do this work. The other suggestion was, that the medical curriculum should be extended to five years. He feared that with the attractiveness of the early studies a larger proportion of these students than was desirable might be so won that their energies would be shunted away from medicine altogether. An intermediate plan suggested itself to his mind—a plan which he had tried to expound twenty-five years ago. This consisted in the adoption of a system by means of which the scientific and the practical training of their students could be made so far to run side by side. It was difficult to make such a radical change in old-established institutions, such as Glasgow or Edinburgh, but he thought it could be done in the new school, on whose behalf he was speaking. If successfully adopted, it would go far to modify the stereotyped ways and traditions of older medical colleges and hospitals. The conjoined system of scientific and hospital training under tuition might occupy two years, and

then the student would be free to devote himself, fully and well-preparedly, to the more practical side of his studies.

### The Medical Digest.

THE accompanying note from Dr. Neale, editor of "The Medical Digest," speaks for itself, and will be received with interest by our readers. We are heartily glad it is his intention to publish "the first appendix" a year earlier than he at first anticipated. To every medical man "The Digest" must prove of the utmost service as a work of reference, a useful councillor in times of doubt and difficulty, when consultations may be hard to obtain; whilst to the writer on medical subjects, the work is simply indispensable if he desires accuracy of knowledge as to what may have been already done in connection with the subject engaging his attention. As one grasps the scope of the work and becomes more familiar with its use, the more indispensable does it become, and the sense of admiration and wonder deepens at what Dr. Neale has accomplished; and we trust that he will receive a ready response to his invitation to our readers to point out any mistakes they may have noticed, and also, that when the book is brought out, he may be encouraged in the work he has undertaken by a still wider circulation and support.

SIR,—Considering that during the past four years so much has been written on medical science, it has been suggested that it would be acceptable to many if the first appendix to "The Medical Digest" were to be issued at the end of 1885 instead of at the close of 1886 as originally proposed.

I wish upon this point to elicit the opinion of yourself, and, through your journal, that of those interested in the subject. A post card addressed to myself, or to the publishers, Messrs. Ledger, Smith, & Co., St. Mary Axe, London, E.C., expressive of such opinions, and noting at the same time, any needed corrections in the edition of 1882, will oblige.

Yours truly,

RICHARD NEALE, M.D.

60 Boundary Road, South Hampstead,  
June 26, 1885.

### Nephrorrhaphy followed by Nephrectomy.

At a recent meeting of the Philadelphia Academy of Surgery an important communication was read by Dr. D. Hayes Agnew on a case of floating kidney, in which he had first fixed and subsequently removed the wandering organ. The patient was a man, *æt.* 32, who had suffered a severe strain while lifting a heavy weight, this being followed by sharp, deep-seated lumbar pain. This occurred in 1878, and examination revealed a moveable tumour having the outline of the kidney; and various mechanical appliances for its fixation were tried without success. In 1884 the man returned to hospital in a pitiable condition from pain and distress, which nothing but large quantities of morphia daily sufficed to relieve, and on October 20 nephrorrhaphy was performed. A linear incision four inches long, parallel with the outer edge of the erector spinæ muscle, gave access to the kidney, which, after breaking up the fatty tissue surrounding it, was fixed by stitches through its capsule to the edges of the parietal wound. After recovery from the operation comfort was experienced for about a month, when all the

old painful experiences once more returned; and on April 23rd of the present year nephrectomy was performed successfully, uninterrupted recovery ensuing, and being completed in four weeks from the date of the operation. Dr. Agnew removed the kidney through an opening made by means of two incisions; one, an inch below and parallel with the last rib, and five inches long; the other extending from the first almost to the iliac crest, parallel with the erector spinæ. The ureter and the vessels were separately included in two double ligatures of silk previously boiled in carbolic water; only two or three vessels connected with the external parts required tying, the material used being catgut. A drainage tube was passed to the bottom of the wound, and the edges of the latter secured with silver wire sutures. Aseptic precautions were observed in both operations.

### Food Reform.

A SERIES of demonstrations in connection with the objects of the Bread Reform League took place last week at the Parkes Museum of Hygiene, Margaret Street, W., when a considerable number of persons availed themselves of the opportunities afforded for learning to what extent cheap foods may be utilised for nutritive purposes. It was pointed out that a pennyworth of ordinary vegetables, when properly prepared, may be converted into a meal for one person, possessing qualities not only nutritious in a high degree, but as well of a most palatable nature; and in pressing this truth upon the people the active officers of the Food Reform League are doing work the value of which cannot be over-estimated. These ladies and gentlemen propose now to extend the soup-kitchen movement by issuing tickets entitling the holder to a pennyworth of food for each ticket, the contents of the packets being such as may, with a little care, be converted at home into a simple nutritious and appetising meal. It is hoped that by this means the poorer classes may be brought to appreciate the importance to themselves of the many cheap articles of diet accessible to, but at present almost neglected by them; and that they may gradually be induced to give attention to the rules by attending to which anyone may easily prepare for home use the numerous forms of cereals and vegetables to be obtained at a small pecuniary outlay.

### The Liabilities of Landlords as to Drainage.

A CASE has recently been decided which is of the utmost importance to householders, as showing the view of the law as to the responsibilities of landlords in relation to the sanitary condition of the houses let by them. It arose out of a claim made by the tenant of a house in Auckland Road, Upper Norwood, who stated that he took the premises in question on a three years' agreement, on the understanding that the drainage arrangements were satisfactory in all respects. The landlord's assurances to this effect, moreover, were based on the report of the sanitary surveyor of the borough of Croydon, in which the house in question is situate, this officer having paid a visit of inspection to the place with a view to deciding whether the requirements of the sanitary authorities had been complied with. Notwithstanding, however, soon after he commenced to live in the

house, several of the plaintiff's servants and members of his family were seized with illness engendered by sewer-gas poisoning, and in the result his wife succumbed a victim to this affection. As her husband enjoyed an income of £1,000 a year during the life of his wife, which ceased at her death, substantial damages were sought on this account, and also a sum of £228 expended in connection with removal and other similar expenses. The jury found for the plaintiff, and in addition to the £228, awarded him also £2,000 as a solatium for the loss sustained through the death of his wife, thus throwing the responsibility of the occurrence on the landlord, who was held negligent of his duty towards his tenant by omitting to take necessary precautions in respect to the drainage of his house. It was proved in evidence that the construction of the sewer-pipes and traps was most defective, and that under the circumstances the escape of gas from them could not fail to be a serious source of danger to the inmates of the house. This instance is but one of many that might be cited, all tending to show the danger that is constantly experienced by dwellers in the suburbs as well as by inhabitants of towns; and until a definite system of inspection of every new house is insisted on, and until property owners are forbidden to let their houses without a certificate of sanitary excellence from a *properly qualified* inspector, there can be no assurance felt that the drainage of even high-class dwellings is carried out in a way to ensure the protection of their inmates from the evil effects of escaping sewer-gas. This question deserves, and should receive, State consideration.

#### London University M.D. Degree.

A DEPUTATION from the Metropolitan Counties Branch of the British Medical Association, consisting of Dr. Bristowe, and Messrs. Jonathan Hutchinson, Morratt Baker, Pearce Gould, and Macnamara, waited on the Senate of the London University on Wednesday last, in connection with the scheme for making the M.D. degree more accessible to metropolitan students. The deputation suggested modifications in the matriculation examination, and wider choice of subjects by candidates, and that failure in a single group of subjects only should entail re-examination in that subject alone in which failure took place. An important point was raised in a request that in future candidates for the degree should be allowed to count the curriculum from any time, and not be bound as at present to do so after matriculation. Uniformity of examination was also asked for.

#### The Out-Patient System in London.

A COMMITTEE of the Council of the Metropolitan Counties Branch of the British Medical Association was appointed some time since to consider whether it would be advisable to charge small fees to hospital out-patients. The sub-committee circulated the following questions:—

1. Do you consider that the exaction of a small payment for medicine, with a careful registration of each applicant by the various hospitals, would be an advantage to the general practitioner? 2. Do you think it would induce many patients who now seek gratuitous advice at hospi-

tals to consult medical practitioners for their ailments? 3. Do you consider that the bulk of the cases which seek relief at general or special hospitals and free dispensaries would suffer from the exaction of a small payment for medicine? 4. Do you consider that the introduction of payments in the out-patient department of our hospitals, and the abolition of free dispensaries, would tend to promote the so-called "private dispensaries," or do you think it would tend to the multiplication of provident dispensaries of a better class? It is recommended as a result of the discussions on the subject, that "all hospitals should adopt the plan carried out at the London Hospital, of an inquiry into the circumstances of out-patients being entrusted to a paid officer of the hospital, and that governors should cease to grant out-patient letters unless to persons whom, from their personal knowledge, they know to be deserving, and in a condition to require hospital relief."

The recommendation of the committee is both wise and practicable, and, we hope, but hardly expect, that it will be carried into effect. If the hospital authorities have a real desire to check the abuse of the out-patient system, and if the governors are willing to surrender their little bit of ticket-giving patronage, it is quite easy to impose the necessary checks against imposition. The simple knowledge that questions will be asked will, at once, relieve the hospitals of most of the well-to-do people who sponge on them. But then there is the danger that, if a small fee be accepted, mean people will obtain medical aid by paying a few pence who could perfectly well afford to pay pounds, and against such a system an equal degree of vigilance will be necessary.

#### Surgeons as Cover to Quacks.

IN the Bow County Court a case under the provisions of the Apothecaries' Act was last week decided. The Society of Apothecaries sought to recover a penalty of £20 from a Mr. Tulby, accoucheur and dealer in patent medicines, of Poplar, for having acted as an apothecary without being duly qualified. In stating the case, Mr. Glyn, the counsel for the Company, said the proceedings were taken under the Apothecaries' Act of 1815. The defendant would contend that he was beyond the Act, because he carried on business conjointly with a surgeon; but a surgeon had no more right to act as an apothecary than an ordinary druggist. Witnesses were called to show that either they themselves or their children had been treated medically by the defendant. He had sometimes called at their houses, and they paid for the medicines supplied. For the defence it was endeavoured to be proved that the defendant did not compound or prescribe any medicines, and that he merely acted as assistant to a surgeon, in which capacity he was entitled to do what he had done. The jury found that the defendant had acted illegally as an apothecary, and the penalty £20 with costs.

If the learned counsel for the Apothecaries' Company is accurately reported to have stated that "a surgeon has no more right to act as an apothecary than an ordinary druggist," we must very emphatically dissent from his reading of the law. The 31st section of the Medical Act says:—

Every Person registered under this Act shall be entitled according to his Qualification or Qualifications to practise Medicine or Surgery, or Medicine and Surgery, as the case may be, in any Part of Her Majesty's Dominions, and to demand and recover in any Court of Law, with full Costs of Suit, reasonable Charges for professional Aid, Advice, and Visits, and the Cost of any Medicines or other Medical or Surgical Appliances rendered or supplied by him to his patients.

The words "according to his qualification" may be interpreted so as to prohibit a pure surgeon from practising as a physician, and *vice versa*, although we know that no such distinction between lines of practice has ever been established either by law or by custom, but in any case it is clear from the words of the clause that, whatever he practises, the surgeon is entitled to recover the "cost of medicines."

### The Reform of the Queen's Colleges.

THE following is the neat arrangement which the reviewer of the Report of the Queen's Colleges Commission offers for the approval of the readers of the *British Medical Journal*:—"To our mind, the true solution of the difficulty must be met in some such way as this. Hand Cork, as a medical school, and Galway, as an arts college, over to the Royal University; affiliate them to it, as these colleges were once affiliated, and actually established, as university colleges of the late Queen's University. Restore the late Queen's University, or create an university upon exactly the same lines in Belfast, to which the present Belfast Queen's College, with more liberal endowments, should be constituted an University College, precisely as it was before the passing of the late Act. Everything points to the necessity for creating a great Northern University in the commercial capital of Ireland—an university, however, beyond the dangers or possibilities of sectarian narrowness or exclusiveness; open to all, and specially adapted to the educational wants of the hard working and industrious middle classes of Ulster, who have eagerly availed themselves hitherto of the advantages which the State has afforded for academic training." Bravo, Belfast! Let us hope that, when the "great Northern University" is established, adequate endowment will be provided for a Professorship of the Trumpet, in which case the *British Medical Journal* will be able to suggest as its occupant an eligible performer on the instrument.

### Uterine Fibromata and Castration.

DR. W. WIEDOW, a dozent in the University of Freiburg, contributes some statistics on the above subject to the *Archiv f. Gynæk.*, Bd. 25, H. 2. The cases embraced in his paper number 149; 15 died in consequence of the operation—certainly rather a high percentage—10 per cent. Some months after the operation 76 could be considered as cured, whilst in 52 others, after the lapse of a year, a decided improvement had taken place, either in diminution in the size of the tumour, or in lessened hæmorrhage. He considers fibrocystic and pediculated sub-serous tumours of the uterus unsuitable for the operation. Myotomy here affords the only effective treatment. Removal of the Fallopian tubes *alone* is not a proceeding to be recommended.

### Testimonial to Dr. F. F. MacCabe, late Local Government Board Inspector for Leinster.

ON the appointment of the above-named popular gentleman to the General Prisons Board, the Poor-law medical union and other officers of the districts which had been under his charge resolved to present him with a substantial token of their appreciation of his great ability as an able and courteous official as well as of their esteem for him personally. With this view a committee of the several subscribers was formed, consisting of Dr. Davys, J.P., Chairman, and Drs. Neary, Usher, and Chapman, with Messrs. T. H. Atkinson, J. D. Cope, and T. Phelan. This committee met on several occasions, and finally on the 25th ult. at the Royal College of Surgeons, when, assisted by the presence of Sir Charles Cameron, a magnificent silver tea-tray and drawing-room clock—which, by the way, are as chaste in their design as they are intrinsically valuable—were decided on as being the most suitable as presentations. An address to be illuminated, submitted by Dr. Davys for approval of his fellow-members of the committee, was adopted, and which when framed, and out of the hands of the artist, will be presented with the above to Dr. MacCabe. We have no doubt that the intended recipient is fully deserving of this thoroughly practical expression of the estimation in which he had been held whilst in the service of the Local Government Board, and we consider it eminently to the credit of those Poor-law officers who took such an active part in this movement.

### Medical Appointments by the Lord Lieutenant of Ireland.

THE Earl of Carnarvon, Lord Lieutenant, has appointed Mr. Hamilton, Professor of Surgery and Councilor in the Royal College of Surgeons, and Surgeon to Steevens's Hospital, Dublin, to be Surgeon to His Excellency, and has appointed Dr. Jacob, Professor of Ophthalmology in the Royal College of Surgeons, and Ophthalmic Surgeon to the House of Industry Hospitals, to be Surgeon Oculist in Ordinary to His Excellency.

### Parliamentary Representation of Edinburgh and St. Andrews Universities.

AT a meeting of the Liberal Association of Edinburgh and St. Andrews Universities, held last week, it was resolved to ask Mr. Erichsen, Surgeon Extraordinary to H.M. the Queen, and late President of the Royal College of Surgeons of England, to become a candidate for the representation of these Universities. Mr. Erichsen is a Graduate of the University of Edinburgh. The feeling is strong that, if he consents to stand, a large proportion of the medical votes will be recorded in his favour.

ACCORDING to Dr. Gordon the circulation of the blood was familiar to the Chinese physicians 2,000 years ago.

WE understand that Dr. Graham Brown, of Edinburgh, has just joined Professor Roy, of Cambridge, and Dr. Skerrington, in order to proceed to Spain as Commissioners from the Royal Society and the Association for the Advancement of Medicine by Research, for the investigation of cholera.

### Teeth Swallowing.

DR. J. W. LANGMORE, editor of the journal of the British Dental Association, asks our aid in making known the need this Association has of reliable statistics relating to cases of teeth-swallowing which are constantly being reported in the medical journals, and the importance of a proper technical description of the plate being given. In most cases it is simply mentioned that the patient swallowed "a small plate," or a plate with two teeth or three teeth. No doubt, in a large number of instances, the patient is to blame for wearing a denture which no longer fits properly, or of which some of the attachments are broken. Still it would be very desirable, he remarks, to ascertain what class of dentures are the most dangerous; and if the medical practitioners who meet with such cases would get some dental friend to furnish a clear description of the plate, some very valuable statistic might soon be accumulated, and the experience thus gained would probably enable dental surgeons to guard more effectually against the occurrence of these accidents.

### Comfort for Anti-Vivisectionists.

THE Report of the Vivisection Inspector for England is a very amusing document, and reads like an ironical squib upon the anti-vivisectionists. The British public is gravely assured that the plunging of thirty stickle-backs into distilled water is not an experiment which need excite humanitarian horrors, and their apprehensions are calmed by the solemn assurance of the inspector that the prick of a hypodermic needle in a frog's leg is not—even when performed without anaesthesia—a degree of cruelty which would require the interference of the law for its suppression. The total number of licences for physiological experimentation during 1884 was 49, and the number of experiments performed was 145. Of these 99 consisted simply in the introduction of a virus; 24 were experiments in cases of suspected poisoning; 10 were experiments on the action of certain fungi upon fish, and 5 on the effects of absolutely pure water upon fish.

### Vaccination.

ANTI-VACCINATIONISTS will be little edified with the conclusions of the German Commission on the Vaccination Question which have been recently submitted to the Reichstag:—

1. One attack of small-pox, with rare exceptions, confers immunity from the disease.
2. Vaccination affords similar protection.
3. The duration of this protection varies within wide limits, but amounts on the average to ten years.
4. To obtain sufficient protection two developed marks are needful.
5. Re-vaccination should take place after the lapse of ten years.
6. The vaccination of the surrounding population increases the relative protection of the individual, and vaccination has, therefore, not merely a personal but a general value.
7. In vaccination with human lymph the danger of the transfer of syphilis, though small, is not absolutely excluded.

8. Since the introduction of vaccination there has been no demonstrable increase of diseases which can be regarded as a consequence of vaccination.

### Conversazione of the London College of Physicians.

ON Wednesday last the annual conversazione of the Royal College of Physicians of London was held in the spacious rooms of the College building in Pall Mall East, and proved one of the most successful of these pleasant *réunions*. The President of the College, Sir Wm. Jenner, Bart., received the guests on their arrival, and during the evening from six to seven hundred visitors were present. An agreeable feature of the entertainment was a selection of music admirably rendered by a military band, and other attractions were afforded in a choice collection of paintings, a beautiful display of flowers, and a number of zoological and other specimens. Dr. Cobbold kindly lent an important and valuable collection of entozoa, which formed an object of interest to many present. Altogether the evening was a most pleasant and enjoyable occasion.

### The New Albany Memorial Hospital.

H.R.H. THE PRINCE OF WALES on Saturday last opened the Albany Hospital for the Paralysed and Epileptic in Queen's Square, Bloomsbury. The new hospital, site included, will, when completed, have cost upwards of £80,000, all of which, except about £700, has been subscribed. The Hospital was first established in 1859, under the name of the National Hospital for the Paralysed and Epileptic, and numbers on its staff some eminent members of the profession in London. To change the name to the Albany Memorial Hospital is, we think, a mistake. True H.R.H. the late Duke of Albany was President of the Institution, and took an interest in its work, but the name in a few years will not unnaturally be forgotten in connection with the hospital, and will possess, therefore, no significance. The building when completed will be a very handsome structure in two ranges, styled the east and west blocks, with a third and smaller range called the Princess Christian. Considerable interest was manifested in the proceedings on Saturday, and a good sum was presented in purses to the Princess of Wales by lady sympathisers in the work.

A STATUE of Linnæus was formally inaugurated at Stockholm on May 13th.

A NEW chemical laboratory and museum are to be built in connection with Cambridge University at a cost of £70,000.

THE returns of the past fortnight show a very decided decrease in the number of persons attacked with small-pox in the metropolis.

WE regret to learn by telegram from Suakim that Surgeon G. M. Russell, Army Medical Department, died of sunstroke on Friday last.

THE Lord Chancellor for Ireland has appointed Dr. John Lentaighe Medical Visitor in Lunacy, vice the late Dr. James Stannus Hughes.

DEPUTY SURGEON-GENERAL OLIVER BARNETT has been appointed Principal Medical Officer on the Staff of Major-General H. A. Smyth, commanding the Woolwich district.

THE balance of the Darwin Memorial Fund, after paying for the statue and medallion, will be made over to the Royal Society to be invested, and the dividends or interest to be applied for the promotion of biological research.

THE Japanese Village, recently burnt down, having proved a great success, there is to be another of a similar nature in London, called the Indian Native Village, in which the habits, customs, and amusements of the natives are to be seen in every-day life.

M. MAGNAN cites a number of cases of madness among anti-vivisectionists. One woman first renounced animal food, then took in all stray dogs, and finally went round to the butchers, begging them not to slaughter any more cattle. She became finally mad, and was received as a patient at Charenton.

THE King and Queen's College of Physicians in Ireland has called upon Mr. Robert Locke Evans, one of the Licentiates of the College, to surrender his diploma, because of his having, in spite of previous warnings, and in defiance of the opinion of the College, advertised by hand bills that he gives advice and medicine for 6d.

INFORMATION has been received of the unexpected death of Dr. Davis Porter, army surgeon, at Wady Halfa, Egypt. He was nephew of the Rev. Dr. Porter, of Queen's College, Belfast, and volunteered for the Soudan, being attached to the 4th Dragoon Guards. He was the principal of the Wady Halfa Hospital, where he died from dysentery.

THE Council of the Royal College of Surgeons in Ireland has withdrawn the diploma in dental surgery granted to Mr. H. F. Partridge, because of his continued violation of the written undertaking against advertising which he gave to the College when he received the licence in dental surgery. His advertisements were published in connection with the so-called Ladies' Dental Institution in Kensington.

DR. FLEISCHL, of Vienna, is recently reported to have found in cocaine a rapid and satisfactory cure for alcoholism, morphinism, and allied habits. The nervous symptoms which arise upon either withdrawing the drug abruptly or by degrees are treated by the hypodermic administration of the muriate of cocaine. It is claimed that in ten days a cure may be effected. The dose is from a quarter to half a grain dissolved in water.

V. HORSLEY, F.R.C.S., in a lecture delivered at the Royal Institution on the "Motor-Centres of the Brain and the Mechanism of the Will," showed that as a rule both cerebral hemispheres are engaged at once in receiving and considering one idea; that under no circum-

stances can two ideas either be considered or acted upon attentively at the same moment; that the brain is a single instrument, and that our idea of our being single individuals is due entirely to this single action of the brain.

SURGEON-MAJOR TOBIN, F.R.C.S.I., of the Army Medical Department, an old student and resident assistant at St. Vincent's Hospital, Dublin, has been appointed to the additional assistant surgeoncy recently created. Mr. Tobin was appointed in 1879 Assistant Professor of Military Surgery to the Army Medical School, and put in charge of the Surgical Division of the Royal Victoria Hospital, Netley. Last year he spent several months in the schools and hospitals of Paris, Vienna, and Berlin, and subsequently he went out to the Soudan as "field-surgeon" to General Graham's expeditionary force. His period of office at Netley having expired, he retires to civil life on a twenty years' service pension.

## Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

ABERDEEN ROYAL INFIRMARY AND THE TREATMENT OF FEVER PATIENTS.—Following closely on the action of the managers of the Edinburgh Royal Infirmary and the directors of the Sick Children's Hospital, it is understood that a strong feeling exists among the managers of the Aberdeen Royal Infirmary that fresh provisions should be made by the local authorities for the reception of fever cases. A meeting of the president and managers of the Royal Infirmary and Lunatic Asylum was held last week for the consideration of a proposal by which fever and other infectious cases should be excluded from the hospital. It was maintained that, in terms of the Public Health Act, the local authorities were bound to arrange for the treatment of these, and that their treatment in the Infirmary involved a mal-use of funds which public charity had devoted to other ends. A resolution was finally passed, by which a committee of managers was empowered to inquire and report as to what arrangement could be made with the local authority. There seems little doubt that other large towns will speedily follow the example of Edinburgh.

PRESENTATION OF A PARK TO THE BURGH OF GOVAN.—The densely peopled Burgh of Govan has just been the recipient of one of the most munificent and most wisely-selected gifts. On Saturday afternoon, Mrs. John Elder presented the inhabitants with the means of health and enjoyment in the form of a public park. The opening ceremony was of the happiest character. Lord Rosebery spoke on behalf of Mrs. Elder, and in doing so, recalled the many beneficent works which the Elder family had already performed. In this last act of generosity he recognised especial wisdom. Mrs. Elder had this day preserved for ever to this crowded district a breathing space of indescribable value. He questioned whether movements of this character must not precede any attempt at improvement in the housing of the working populations. Before improving their dwellings, they must do something to improve and to raise their lives. The park is situated at the end of Govan, opposite the ship building yard of Messrs. John Elder & Co. It measures about 37 acres in area, and is nearly square in form. The internal arrangements are of the best description. The cost of the whole is about £50,000.

**THE LATE DR. WOTHERSPOON, LOCKERBIE, DUMFRIES-SHIRE.**—Dr. John Thompson Richardson Wotherspoon died at his residence, The Green, Lockerbie, on the 25th June, after a brief illness. The deceased physician enjoyed the confidence of a very large circle of patients, by whom his talents and skill were much appreciated. He was a Licentiate of the Royal College of Physicians and of the Royal College of Surgeons of Edinburgh. Previous to settling in Lockerbie, he practised for some years in the South of England. He has passed from our midst, while still apparently in mid time of his years, having finished his studies in Edinburgh just twenty years ago.

## Sanitary Department.

### REPORT OF THE MEDICAL OFFICER OF HEALTH OF NEWCASTLE FOR 1884.

THE Report for 1884 on the sanitary condition of the large and important city of Newcastle is before us. Mr. Armstrong has spared no pains to make his Report as useful as possible, and though he has thereby sacrificed literary elegance to soundness of information, the result of this self-denying process must be regarded as a distinct gain to the science of urban sanitation. The birth-rate during 1884 was 40.1, and the death-rate 23.5 per 1,000; this latter has been less in only five years of the last seventeen. Diarrhoea was the most fatal zymotic disease, no less than 164 deaths being recorded from this disease alone, of which 117—or 70 per cent.—took place in the third quarter of the year. The deaths of infants under one year was 949, a considerable increase on the number in the three previous years. The clauses of the Improvement Act relating to notification of infectious diseases appear to work well at Newcastle if one may judge by the increased number of notifications during 1884, as compared with 1883 (equal to 30 per cent. more). No less than 17 cases of typhus came under the notice of the health department in the year, which seems to show that the sanitary circumstances of dwellings in Newcastle are not what they should be. More than two thousand cases of scarlet fever came under the cognisance of the Sanitary Authority during the same time, an instance of the practically endemic character of this disease in large centres of population. As to diphtheria, 76 cases were notified, and we observe that 25 of these (or one-third) occurred in February and March. Mr. Armstrong devotes a large portion of his report to a consideration of the various modes in which infectious diseases are communicated. Foremost amongst the agencies of dissemination he places the existence of large numbers of *tenement* houses, with the accompanying deficiency or absence of isolation. He supports this by reference to carefully prepared statistical evidence. Instances of transference of infectious maladies by visiting at infected houses, by acting at funerals and the like are given. Small-pox was introduced into the Newcastle Infirmary by the admission of a patient suffering from the disease, though at first this was alleged to have been due to the milk supply, a case having occurred at the dairy whence the Infirmary milk was obtained. A railway porter who received tickets from persons frequenting a railway leading to a neighbouring town infected by the disease was attacked. An account is also given of small-pox concealed at a dairy, the owner of which was prosecuted for failing to notify the case. It being found that enteric fever was prevailing at a dairy farm which supplied milk to the city, steps were taken to prohibit the delivery of the milk. Interesting details are given as to scarlet fever; amongst other matters it was found that 70 per cent. of the infected houses had no means of isolating the sick room from the rest of the premises, and that in more than one-half, no means of preventing infection were taken. Bailiffs appeared to have entered infectious houses, and to have seized infected furniture, but not without proceedings being taken by the Sanitary Authority. On scarlet fever becoming rife among scholars the sanitary officials promptly communicated with the school authorities with reference to prohibition from attendance, but Mr. Armstrong comments on the fact that the Government grant is withheld in such circumstances, which causes the school authorities to be chary of complying with the wish of the health officers. A

summary of occupations followed by people living on infected premises shows that dealers in house decorations, machine workers, and conveyers of goods and messages were the most numerous in the order given. Mr. Armstrong states that 70 per cent. of infectious disease in the city occurred in *tenement* property, and that consent to remove cases to hospital was obtained in only a small proportion of cases. He therefore insists on the urgent necessity for hospital accommodation. Reference is made to the energetic action of the Port Sanitary Authority in view of the possible advent of cholera. This comprised means of obtaining early information of the progress of the disease, strengthening of the Inspectorate, and provision of a floating hospital. An important house-to-house inspection of the district was made in 1884, the result being that more than 12,000 nuisances were abated, being more than double the number in 1883. Five outbreaks of infectious disease in the families of dairy men were reported, but prompt measures were taken to limit the disease to these families. Cowsheds and slaughter houses were also carefully inspected during the year.

A series of instructive tables are appended to Mr. Armstrong's Report. It would appear from these that phthisis was the most fatal disease during 1884, the next in order being diarrhoea, scarlet fever, and whooping cough. Mortality according to season showed that this was greatest in the third quarter of the year, the deaths being 113, 84, and 125 in the first, second, and fourth quarters respectively, whilst there were 173 in the third. Mortality according to age showed the usual excess of infants under 1 year and adults over 60. The admissions into the Fever and Small-pox Hospitals were greatest in March and the deaths most numerous in April. Mr. Armstrong follows up his able Report on the general condition of the large city entrusted to his care by a special report on certain streets in Newcastle, in which he particularly assails the condition of the numerous cellar dwellings abounding in these localities, and of the "well-rooms." These are rooms without openings other than the door and window, which are both placed in the same corner of the room. Elaborate plans for remedying the evils induced are appended.

### CHOLERA: A TIMELY EXHORTATION.

IN view of the possibility of cholera reaching our shores, Dr. Wm. Carter, Medical Officer of Health for West Derby district, has issued the following circular, which has been freely posted up, and also delivered to the householders throughout the district. House to house instructions are not likely to go entirely unheeded, and the example here set might be advantageously extended elsewhere. The following is the text of this circular:—

"As it is thought that cholera may possibly visit England during the present year, a few words as to the best means of preventing it from attacking our homes may be useful.

"The very best preventives are complete cleanliness of the house and its surroundings; cleanliness of the body; a pure drinking water; and abundance of fresh air.

"In order to obtain these, the house and yard should be often cleansed, the walls of the yard and ceilings of rooms should be whitewashed; all bits of vegetable, or bits of fish or meat, or the entrails of fowls, &c., should be burned and not allowed to lie about on floors or in yards, or to be put into middens there to rot and pollute the air; the drains should be free from obstruction, and should give off no bad smell; the drinking water should be obtained directly from the main, and not from cisterns or from wells sunk near pigstyes, or other places likely to make the water foul; middens should be frequently emptied, and water-closets well flushed and perfectly clean.

"If these rules are carefully carried out in every house in the district, cholera will not visit us even if it should come to England.

"If you have any fear that the drains are out of order, or if there is any nuisance on your premises, you can have them immediately attended to by sending a message to the inspector of nuisances, at the address at the top of this circular."

DR. HENRY CROLY, a much esteemed and resident practitioner at Rathfarnham, co. Dublin, and one of the Examiners in Midwifery in the Royal College of Surgeons in Ireland, has been appointed to the Commission of the Peace for the County of Dublin.

## HORRIBLE LONDON!

ON Monday the *Pall Mall Gazette*, which at one time was deemed a highly respectable journal, indulged its readers with five pages of "revelations" on the shady side of London life, which, with the excitement and tumult occasioned by the shouting of hundreds of hoarse-throated newsboys, fell like a bombshell among the peaceable public. Whatever else these "revelations" may be they are certainly startling, and this in a fashion almost if not quite unknown in the English press. The influence of Zola, the founder of the so-called *pornographic* school of literature is rapidly spreading, and may indeed be said to have reached the pernicious phase, if those respectable journals we have hitherto been accustomed to read in our homes take to treating the public to circumstantial details respecting the alleged violation of a given number of girls nightly. Most people even of a robust constitution will deprecate the calling of this spirit from the vasty deep, since it is difficult to see what good end can be attained. The colours, too, have purposely been chosen of an intensely vivid hue, and the whole article (which we are promised is only one of a series) bears the stamp of being a vulgar attempt to secure a ready sale for the particular journal, with, we fear, very little regard for the "*Salus populi suprema lex*" side of the question.

WE regret to learn that a fresh case of small-pox has occurred in Dublin, emanating from the cases recently reported by us as having occurred at 71 Pembroke Road. It is stated that some of the clothes belonging to one of the previous cases were sent to one of the suburban laundries, and that shortly afterwards one of the *employés* was attacked with the small-pox, and is now in Cork Street Fever Hospital.

WE understand that, by an inadvertence, the name of Dr. Thomas Bodkin, of Tuam, was included in the obituary list of the "Irish Medical Directory" for 1885. This error arose, we believe, from the fact that Dr. Bodkin's name was included amongst those erased within the year 1884 from the "Medical Register," he having, we assume, omitted to reply to the letters of inquiry addressed to him by the Branch Medical Council. We are glad to state that Dr. Thomas Bodkin is still alive and in active practice at Tuam.

## Correspondence.

## MR. ERNEST HART'S PARLIAMENTARY CANDIDATURE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I can hardly believe the statement which I find made positively in a contemporary, that Mr. Ernest Hart, the editor of the journal of the British Medical Association, has sought to make his way into Parliament by selling his principles to the syphilis-propagation agitators. If it be so, I must say that, however anxious the profession may be for an increase of medical representation in the House of Commons, and however they might be disposed to recognise very special claims in Mr. Hart, it is to be hoped he will not succeed in his candidature, and that no medical voter of the Mile End Parliamentary division will record his vote for him. Either the editor of the *British Medical Journal* believes in the necessity or expediency of checking the dissemination of venereal disease by legislative means or he does not. If he does the treaty into which he has entered with the anti-contagious diseases people is a gross violation of principle and a practical retraction of all that has been editorially written in the journal. If he does not, then he is certainly not the proper exponent of the Association which declared at the Liverpool meeting its firm belief in the necessity for

such legislation and its absolute disbelief in the statements of the syphilis-propagation agitators. If Mr. Hart acquires the pendant of M.P. by thus surrendering to the enemy, what is to prevent him doing the same to secure the anti-vaccinator's vote? and why should he not go out as the platform advocate of the anti-vivisectionists? and if the censor of the morals of the profession thinks it allowable to insult the general feeling of his medical and scientific brethren in order to secure the suffrages of those whose habit it is to slander medical men, is there anything at which a doctor-candidate for Parliament should stop to secure his election?

A MEMBER OF THE ASSOCIATION.

## THE NEW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Last week you published a very learned letter from Mr. Stuart Nairne, of Glasgow, controverting certain statements which you had thought proper to make on the outbreak of another medical society in Glasgow. I am quite of opinion that there are many objections to such a society; there is at present a Medico-Chirurgical Society in Glasgow—an old and respectable society—which fails to receive adequate support from the profession; as its name implies, it covers such subjects as would be discussed by the new society, and if this segregation of the profession into endless societies is to be encouraged the creation of every new one is but another knife in the throat of the old Medico-Chirurgical Society. Rightly or wrongly, there is a growing opinion that under the guise of gynæcology much demoralising and unprofessional conduct is carried on. Of this nature I regard many of the "operations" resorted to by the gynæcologist, such as spaying, os-slitting, &c., &c.—an easy means of making money, for martyrdom as arising from an "inward complaint" is a most grateful possession of the middle-aged maiden. The necessity for operations is ever at hand, and they are necessarily of such a nature that they are not subjected to the wholesome check of professional or public opinion. Every one has heard of the case of an unfortunate lady who, in one of our large Scotch cities, slipped by accident into the house of a gynæcologist instead of that of his neighbour the aurist, and was there treated for deafness for six months through a vaginal speculum! It is better that gynæcological subjects should be treated at the Medico-Chirurgical Society rather than at a special society, for at the former the healthy restraining influence of the older and less impulsive members of the profession would be highly beneficial, while at the latter one may expect only the unbridled licence of impetuous and self-seeking enthusiasts.

Yours truly,

AN OBSTETRICIAN.

## RECENT APPOINTMENT OF RESIDENT SUPERINTENDENT TO THE CASTLEBAR ASYLUM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The appointment by His Excellency Earl Spencer to this county institution has puzzled many and astonished more. What the motive could be that induced him to ignore the recommendations of the three Irish candidates is difficult to understand, particularly as each of them had lengthened service and first-class records in similar institutions in this country. Lord Spencer has in his two last appointments to Castlebar District Asylum adopted a new and extraordinary rule, viz., that no matter how strong the claims, how numerous the recommendations, and extensive the service and experience, the favourite doctor must first proceed to England, remain there for a few years, and then return and receive the promotion which was denied him while he remained a mere Irish practitioner. In fact, the two last appointments at Castlebar fully bear this interpretation, and like the recent flimsy honours offered to the Irish profession, and very properly refused by its independent members, it means nothing but another effort of studied insult, indicating that at the Castle the opinion prevails that no medical gentleman could be found in Ireland fit for one of those positions. Will the members of the profession tamely submit to this indignity? I hope not, and I trust

that one of our vigilant members of Parliament will bring the whole matter before the House of Commons.

I am, Sir, yours, &c.,

INQUIRER.

[We join our correspondent most heartily and emphatically in his protest against the system which is being introduced into the Irish Lunacy Department of importing officers from England, and ignoring the claims of the assistants to the Resident Superintendent and of the Visiting Physicians of Irish asylums. We know that this system was first introduced at the instance of the senior Inspector of Asylums in Ireland, who recommended an English officer to be appointed to the Limerick Asylum because he desired to introduce into Ireland the English system, under which the Resident Superintendent is everything and the Visiting Physician nothing. The previous Resident had been dismissed from that asylum because of the homicide of a lunatic named Dunford killed by repeated cold baths, and the principle since then has always been acted on that the fewer eyes there are to see what goes on in asylums the better. For this reason the inspectors made new rules, by which they reduced the visiting physician, as far as they could, to a nonentity, and they encouraged certain of the Resident Superintendents in a foolish jealousy of that officer's functions, and in an effort to abolish the visiting office altogether. This effort failed in consequence of the intervention of the Irish Medical Association, but since then the Inspectors have never lost a chance when an appointment fell vacant of importing into the lunacy service an English officer. We regard the transaction as an unqualified job. If the subordinate officers of Irish asylums are unfit for promotion, let the authorities say so, and let them take the responsibility for allowing those officers to be so incapable. If they are not unfit it is a disgraceful job to pass them over when an opportunity for promoting them occurs.—ED.]

THE REPORT OF EXPERIMENTS ON LIVING ANIMALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR

SIR,—Your reference to myself in the paragraph which appears in your issue of July 1st obliges me to point out that the reports in the statement in question do not in any way tally with the facts in the reports of the experimenters themselves, and that an explanation is due on this point either from the Inspector or from the experimenters. It is now too late in the day to go into the question as to whether these experiments confer any benefit upon science or not. A law has been enacted for their regulation, and it is much to be regretted for the honour of our profession that there should be even an appearance of the evasion of that law. If experiments can be justified by the results obtained from them, then there can be no need whatever for concealing either the nature or the number of the experiments. But if mendacious statements are issued, then you may be perfectly certain that the public will speedily be of opinion that everything which has been said against vivisection and against those who practise it is capable of the fullest justification.

I am, &c.,

Birmingham, July 2, 1885.

LAWSON TAIT.

[Referring once more to the Report, and having followed the question with some care, we are at a loss to conceive what grounds Mr. Lawson Tait can have for his assertion "that the reports in the statement do not in any way tally with the facts in the reports of the experimenters themselves." It is clear that he and his anti-vivisection friends care only to take a distorted view of those who seek to carry out the Act with every care and to the best of their ability, and if "mendacious statements are issued," as he asserts they are, then the profession at least know to whom such an

accusation really applies; it certainly does not to the Inspector under the Act, who is known to be one of the most honourable and liberal-minded men in the world of science.—ED.]

PASS LISTS.

University of Cambridge.—At the June examinations for degrees in Medicine and Surgery the following candidates satisfied the Examiners:—

BACHELOR OF MEDICINE (3rd exam.). Part I.—Dr. Anderson, Caius; Dr. Andrews, St. John's; Dr. Brushfield, Caius; Dr. Burd, Caius; Dr. Daniels, Trinity; Dr. Emerson, Clare; Dr. Facey, St. John's; Mag. F. M. Haig, Trinity; Dr. H. E. Harris, Christ's; Dr. H. A. Haviland, Pembroke; Dr. H. G. W. Jones, Downing; Dr. Lynch, Caius; Dr. Nichol, Caius; Dr. Nicholls, St. John's; Dr. Niven, Caius; Dr. P. C. Scott, St. John's; Dr. Smart, Caius; Dr. Trott, Caius; Mag. Walsham, Caius; Dr. Wishaw, Cavendish.

BACHELOR OF MEDICINE (3rd exam.). Part II.—Dr. Anderson, Trinity; Dr. Bull, Caius; Mag. W. Fowler, Caius; Dr. Hillier, Caius; Dr. Reid, Cavendish; Dr. J. M. Clarke, Caius; Dr. S. M. P. Roberts, Christ's; Dr. Stericker, Clare; Pa. F. C. Wallis, Caius.

BACHELOR OF SURGERY.—Dr. Andrews, St. John's; Mag. Haig, Trinity; Dr. Lynch, Caius; Dr. Nichol, Caius.

University of Dublin.—The following Candidates having undergone the necessary examinations, received their degrees at the last meeting of the Senate:—

DOCTOR IN MEDICINE.—Francis George Goodman, Thomas Harrison, William Francis Law, James Ferrier Pollock, John Edward Blakeney Purdon, Rogers Taylor.

BACHELOR IN MEDICINE.—William Ambrose Ardagh, John Bouchier-Hayes, Frederick A. G. Davis, John Marshall Day, Augustus Edward Dixon, William Sinclair Dobbin Robert L. S. Donaldson, William Ireland Donaldson, Alexander Findlater, Cathcart Garner, Edward Wolfenden Gray, Henry John Hadden, Edgar Hogben, William Leah, William Pringle Morgan, Edwin Graves Newell, Alexander Stoney Patton, Walter Croker Poole, George Thomas Revington, John Joshua Russell, Whitely Bland Stokes, Arthur Ernest Switzer, Thomas Du Bedat Whaite, John Darley Wynne.

BACHELOR IN SURGERY.—William Ambrose Ardagh, John Thomas Bouchier-Hayes, Alexander James Boyd, John Marshall Day, Robert L. S. Donaldson, Edward John Farmer, Cathcart Garner, Edward Hogben, Robert Ker Johnston, Robert John Montgomery, William Pringle Morgan, Alexander Stoney Patton, Walter Croker Poole, George Thomas Revington, John Joshua Russell, Arthur Ernest Switzer, Thomas du Bedat Whaite, John Darley Wynne.

LICENTIATE IN SURGERY.—Daniel Conway.

University of Edinburgh.—FINAL EXAMINATION IN MEDICINE.—The following is an additional list of candidates who have passed the final examination at this University. The first list appeared in our last week's issue; those marked with an asterisk having passed with distinction:—

Blair, Robert  
Chetti, Pulicet Parthasaradhi  
Clark, Edmund Wearne, B.Sc.  
Clemow, Frank Gerard  
Collinson, Frederick Wm.  
Cram, John, M.A.  
Dawe, Jas. Henry  
Delepine, Jules  
Dickman, Henry George  
\*Douglas, Kenneth M'Kinnon  
Dow, Wm. Oliphant  
Eaton, Walter Musgrave  
Elder, Wm.  
Eyre, George Graves, B.A.  
Faulkner, Wm. Cooke  
Fischer, Lewis Gordon  
Flaher, Alex., M.A.  
Freeborn, H. S. E.  
Fry, Edwin Sargood  
\*Garvie, John  
Gemmell, John Edward  
Glegg, John  
Glover, Jas. Gray

Gray, A. E. Lampton  
Grier, C. W. Monroe  
Griffith, Thos. Howard  
Gubbin, Wm. B. Thompson  
Haldane, John Scott, M.A.  
Hallows, Stuart Pennington  
Harvey, John Thomas  
Helm, John Hunter  
\*Helme, Thos. Arthur  
Helme, Walter Croft  
Hennasy, Frank Wm.  
Hewland, George Vickerman  
Hill, John Ramsay  
Hirst, Herbert  
Hoffman, Joshua Jacobus  
Home, Wm. Edward, B.Sc.  
Hood, Archibald  
Horsley, Reginald Ernest  
Hughes, Alfred Wm.  
Hunter, Jas., M.A.  
Kingdon, Ernest Cory  
Richards, John

Royal College of Physicians of Edinburgh.—The following candidates have passed their final examination, and have received the Licence (L.R.C.P. Ed.):—

Low, Thomas Pagan, Bath  
Donaldson, James, Lochmaben  
Robson, A. Wm., Birmingham  
Booth, John H. Chesterfield  
Cook, Alex., Rutherglen  
Edwards, John F. H., Birm'gh'm.

Wright, H. E. P., St. Helens  
Gill, Kbt. Chas. G., Burgess Hill  
Cardwell, Thos., Reading  
O'Callaghan, John Cappamore  
M'Manus, Wm., Athlone

Royal College of Surgeons in Ireland.—At a meeting of the Court of Examiners held on the 22nd of June and following days, the under-named gentlemen passed the first half of the examination for the Letters Testimonial of the College, viz.:—

Robert Abraham, Charles R. Batteraby, George O. Burkitt, Jas. E. J. Duffy, George B. Elliott, Martin Fitzgerald, Richard F. Fitzgerald, Edward Garraway, N. J. Gossan, William R. G. Hamilton, Daniel Henigan, J. Maguire, Frederick W. Monell, John J. O'Connor, Edward B. Pooley, Charles J. Rutledge, Michael J. Ryan, and Patrick J. Ryan.

## Notices to Correspondents.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**READING CASES.**—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

**LOCAL REPORTS AND NEWS.**—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

**MR. R. THACKERAY** (Paddington Green).—We cannot accept your communication on any imposed conditions.

**DR. HUSBAND** (Manitoba).—Glad to learn of your safe arrival. We have directed that the *Medical Press* shall be sent you to the address given.

### THE CASE OF DR. BRADLEY.

To the Editor of the *MEDICAL PRESS AND CIRCULAR*.

**SIR,**—As an attentive reader of your journal and commissioner in the sorrows of a brother practitioner, I have to express my thanks for the time and attention devoted by you in laborious efforts to release from a prison cell a victim of illegality and injustice. These are strong words to use indeed; but when a Commons legislator tells us that judges are not infallible, we may be permitted to express our opinions too, after making an exhaustive analysis (qualitative and quantitative) of the facts.

Those facts have been so fully recorded by the *Medical Press and Circular* that it would be a process similar to the excessive drugging of a patient with such useful and potent medicines as tartar emetic to repeat the said facts. So I would now respectfully and urgently suggest to you, Sir, and to your fellow-journalists and the profession at large, to inundate the House of Commons, individually and collectively, with letters and petitions, until from very wearisomeness, if not from justice or pity, our prayers be granted.

Yours respectfully,  
MEDICUS.

**DR. BRANDON** (Griqualand).—Back numbers cannot be sent at the ordinary rate of penny postage. After the lapse of eight days the newspaper rate ceases, and book-post rate is charged. As this latter is 1s. 4d. per lb. to South Africa, the back numbers can only be sent you at the rate of fourpence each for postage.

### FEES FOR HOUSE INSPECTIONS UNDER LABOURERS' ACT.

The Kanturk Board of Guardians has munificently voted one *and sixpence* per house to their medical officers of health for inspections, which sum, we hope, the doctors will leave to the economical guardians for the purpose of paying for their washing. A fair remuneration can be readily and certainly recovered in the County Court. No scale of payment has been fixed either by the judges or the Local Government Board, and the Irish Medical Association advises that such sum per house shall be charged as will represent about £2 2s.—a day's work.

**MR. EDWIN WOOTON** (Kennington).—Regret to have to decline your papers, but the experiments are not of the kind to be of the slightest use to our readers.

### THE SMALL-POX OUTBREAK IN DUBLIN.

To the Editor of the *MEDICAL PRESS AND CIRCULAR*.

**SIR,**—In your issue of the 1st inst., with regard to your notice of the nurse who died of variola in this hospital having been twice vaccinated, she had two large vaccination marks, but, so far as I am able to learn, has been only vaccinated once, and that when an infant.

I am, Sir, yours faithfully,

SYDM. D. CHANDLEE, Res. Med. Officer.

House of Recovery, Cork Street, Dublin,  
3rd July, 1885.

**DR. CORNWALL.**—There is nothing in the prescription to account for the symptoms produced; but if the patient is of rheumatic tendencies an explanation is at once afforded of the painful sensations. In this case careful attention to the diet and clothing, and a due regulation of exercise as to time and season, will probably be productive of beneficial results.

**DR. BRADY.**—The book is a very old edition. Since it appeared several new editions of the work have been published, and that now in circulation is practically an entirely new treatise, added to which it has been revised by successive editors, each of whom has stamped his own views as to treatment and etiology on its pages. You need not, therefore, feel surprised at the discrepancies you have discovered, or may discover in future. They are inseparable from progress.

**THE CAUSES AND TREATMENT OF ALBUMINURIA.—A QUERY!**  
To the Editor of the *MEDICAL PRESS AND CIRCULAR*.

**SIR,**—Will you kindly enlighten me on the following subjects by an answer in the next issue of the *Medical Press*:—1. Is the albuminuria and hæmatinuria caused by constant inhalation of carbolic acid likely to leave permanent Bright's disease? 2. What treatment is most suitable in such cases? 3. How long does the acute stage last?  
W. W.

[1. Yes; of a cirrhotic character. 2. Turkish baths are a great help by relieving the kidneys by a profuse diaphoresis. Failing them,

vapour baths by the blanket, chair, and lamp. Great benefit can be attained by a farinaceous and milk diet, avoiding meat and eggs; this lessens the work of the kidneys. In the early stages benefit may be obtained by local depletion of blood. Avoid diuretic medicines, and, above all, mercurial preparations. 3. This question can be answered only by careful consideration of the circumstances of each individual case.—ED.]

**MR. DAVISON.**—We do not, as a rule, pretend to advise on any point not immediately connected with the practice of the profession, but in this case it is quite justifiable to recommend that you should invoke the assistance of an arbitrator. The facts, as you have communicated them, are of a kind to make such a proceeding especially appropriate.

**MR. ADAMS.**—The course you have pursued is the only one which, under all the circumstances, you would have been right to follow. Whatever consequences may ensue, you cannot be considered to blame. You ought never to have been placed in a position of such extreme embarrassment.

**ALABIC.**—You had better communicate with the Registrar, at the General Medical Council office. As far as he can, we are quite sure that he will assist you; but it is quite possible that the information can only be obtained from the authorities of the institution in America; and we fear you must be prepared to learn that they will decline to afford it to any applicant save the one directly concerned. In this case you can proceed no farther in the matter.

## Vacancies.

**Buenos Ayres.**—Resident House Surgeon to the British Hospital. Salary, £200, rising to £250, with board, &c. Applications to House Surgeon, B. A., care of Burgoyne & Co., 16 Coleman Street, London.

**Chelsea Hospital for Women.**—Resident Medical Officer. Salary, £60, with board. Immediate applications to the Secretary.

**French Hospital, London.**—Resident Medical Officer. Must speak French. Salary, £60. Applications to the Secretary at once.

**St. Thomas's Hospital Medical School.**—Demonstrator of Physiology and Practical Physiology. Applications to Mr. G. Rendle, at the Hospital.

**Sussex County Hospital, Brighton.**—Assistant House Surgeon. Salary, £40 per annum, with board, &c. Applications, with testimonials, to the Secretary, on or before July 15.

**Western General Dispensary, London.**—Assistant House Surgeon. Salary, £68, with apartments. Applications to the Secretary, Marylebone Road.

## Appointments.

**BRAMWELL, H., M.B.,** House Surgeon to the Newcastle-on-Tyne Infirmary.

**DUNGAN, J. T., M.R.C.P. Ed., M.R.C.S.,** Medical Officer for the Barnack and Ryhall Districts of the Stamford Union.

**FENWICK, C., L.R.C.P. Ed., L.R.C.S. Ed.,** Medical Officer to the Ephroe Dispensary of the Strabane Union.

**LEWIS, J. K., M.R.C.S., L.S.A. Lond.,** Medical Officer to the Thorverton District of the Tiverton Union.

**NASON, C. St. B. E., M.D., M.Ch. Dub.,** Medical Officer for the Sixth District of the Upton-on-Severn Union.

**SMITH, F. J., B.A. Oxon., M.R.C.S., L.R.C.P.,** House Physician at the London Hospital.

**THURSTON, E., L.R.C.P. Lond., L.S.A. Lond.,** Curator of the Anatomical Museum, King's College, London, Superintendent of the Presidential Museum, Madras.

## Births.

**EVANS.**—June 30, at Harwich, the wife of Samuel Evans, L.R.C.P. Lond., M.R.C.S., of a daughter.

**WATERWORTH.**—July 3, at 221 New Kent Road, London, the wife of T. H. Waterworth, M.D., M.R.C.S., of a son.

## Marriages.

**CLARK—JAMES.**—July 2, at St. Matthias Church, South Kensington, F. W. Clark, F.R.C.S., of Conich, Yorks, to Gertrude Haughton, daughter of the late Lieutenant Haughton James.

## Deaths.

**CHEPMELL.**—June 24, at Florence (travelling), Edward C. Chepmell, M.D. Ed., aged 66.

**DREMPSTER.**—June 20, at Tremore, Co. Waterford, Charles Carroll Dempster, Deputy Surgeon-General A.M.D., aged 51.

**HIND.**—July 4, very suddenly, at his residence, 184 Euston Road, London, G. Wm. Hind, F.R.C.S., aged 83.

**HOWARD.**—June 28, at Mindenwolfe, Bedford, Edward Howard, Esq., late H.M. 20th Regiment, Deputy Inspector-General of Hospitals, Army Medical Department, aged 69.

**HOWE.**—June 28, at Knowle Vicarage, Warwickshire, John Ernest Howe, B.A. & M.B., M.R.C.S., aged 27.

**MANBY.**—June 30, at East Rudham, Norfolk, Frederic Manby, M.R.C.N., aged 74.

**SAMPSON.**—June 27, at his residence, St. Matthew's, Ipswich, George Green Sampson, M.R.C.S., L.S.A. Lond., aged 81.

**WOTHERSPOON.**—June 25, at The Green, Lockerbie, John T. R. Wotherspoon, Physician and Surgeon.

### THE OPERATION FOR CORRECTING SOME UTERINE DISPLACEMENTS BY SHORTENING THE ROUND LIGAMENTS. (a)

By WM. ALEXANDER, M.D., F.R.C.S.,  
Visiting Surgeon to the Liverpool Workhouse Hospital.

THE operation is a delicate one and differs from nearly all the ordinary operations. It resembles most the ligature of arteries or neurotomies, but from both it differs in many essential particulars; in the former pulsation is a guide, in the latter the characteristic whiteness and, in addition, twitching, often shows when the nerve is found. The round ligament does not pulsate, and is of a pale flesh colour when first seen. It lies embedded in other tissues which, by the inexperienced might easily be mistaken for it. Its white sheen only appears when pulled out.

Beginners sometimes fail to find the ligament through inexperience. I only failed once in eighty cases, and returning to the case later was quite successful. In two cases one ligament in each was adherent, and would not pull out. In both cases the opposite ligament was strong, and the cases are well up to the present. The operation has, therefore, in my hands been very satisfactory.

Dr. Paul F. Mundé describes, in the *New England Medical Monthly*, four cases in which he attempted the round ligament operation. In one he was perfectly successful, in the second he could only with great difficulty get one ligament, and in the third and fourth he could not find any ligaments at all.

A few weeks previously in the *Edinburgh Medical Dr.* Imlach stated that in nearly forty cases he never failed to find the ligaments, and thought only  $\frac{1}{2}$  an inch incision necessary for the operation. If Dr. Imlach minimised matters to an extent that was unsafe for the inexpe-

rienced to follow, Dr. Mundé's conclusions are far more faulty in exaggerating the difficulties and uncertainty of the operation. The author has examined the round ligaments in over a hundred cases on the post-mortem table, at ages ranging from one day to eighty years, and, except in two cases of pelvic adhesions where the ligaments were found but failed to run, no difficulty was experienced in the finding and pulling out.

No one should attempt the operation without first doing it a few times on the cadaver. The best way to make sure of finding the ligaments may be detailed as follows:—

The pubic spine is the first landmark, and can be felt by an intelligent finger under any depth of superincumbent fat. It does not matter much whether the finger can feel the spine clearly or not, provided the primary incision be made within reasonable distance of it, but there need be no serious difficulty in finding it as Dr. Mundé seems to think. From this, an incision is made upwards and outwards in the direction of the inguinal canal for  $1\frac{1}{2}$  to 3 inches according to the fatness of the subject and dexterity of the operator. A considerable thickness of subcutaneous fat is now met with, which must be cut through by subsequent incisions until the pearly glistening tendon of the external oblique muscle is reached. Midway through the fatty tissue an sponerosis sometimes appears so firm and smooth as cause the operator to think he is deep enough, and if he begins to poke about here as I have done and seen others do it is little wonder no ligaments can there be found. The first stage of the operation consists simply in cutting down upon the tendon of the external oblique muscle until it appears clean and shining at the bottom of the wound. If the operator succeeds in hitting the spine, the external inguinal canal with the intercolumnar fibres crossing it can also be seen, if not the aperture now made down to the muscles can be dragged over an extensive area by retractors so that the region can be searched until the ring is found. The finger passed to the bottom of the wound can be used to detect the spine, and the ring outside; the former by its hardness, the latter by its lessened resistance compared

(a) Paper read before the British Gynaecological Society on June 10th, 1885.

with that of the aponeuroses around it. The anatomical knowledge of the operator should always be equal to the recognition of these structures, *i.e.*, the spine and the external abdominal ring. There are other apertures in the aponeurosis and a depression filled with fat below Poupert's ligament that sometimes simulate the external ring. Poupert's ligament below, the intercolumnar fascia running across, and the spine at the inner side are sufficient landmarks. When in doubt a slow, deliberate survey of the position should be taken, and no groping in the dark made, as these are certain to lead to failure. Having clearly isolated the external abdominal ring, and tied or compressed any bleeding vessels, the next step in the operation may be entered upon. The intercolumnar fascia which is generally pushed forwards by the fat and other structures beneath is to be cut through over all the extent of the external ring, and in the direction of its longest diameter—a nerve, vessels, fat, tendinous bands, and the round ligament spring out of the canal immediately. In fat people the quantity of fat conceals all the other structures. No "grabbing" at the mass is now to be practised, as some have recommended. By everting all the structures upwards the round ligament can be seen, generally at the lowest part, and with the white easily distinguished genital branch of the genito-crural nerve along its anterior surface and close to it. The ligament at this stage is more or less round in shape, sometimes rather delicate, but an always readily recognised flesh-coloured structure that might be easily destroyed by forceps rudely and blindly applied. Should the ligament seem very frail, or the operator be doubtful whether he has found it or not, he should take care not to displace the structures or destroy them by searching or pulling. His best plan in such a case is to open up the inguinal canal a little and then re-examine what he supposes to be the ligament. No difficulty in finding the ligament need thus ever be experienced, provided the operator knows what he is about. When the ligament is clearly identified the small nerve on its surface is to be cut through without cutting any of the ligament. Then gentle traction is to be made either by the fingers or broad blunt-pointed forceps. Care must be taken not to break the ligament by such traction. Bands will now be seen holding it to the neighbouring structures. These should be cut through with scissors, the greatest caution being observed to avoid notching the ligament at the same time. With a little patience and perseverance the structure is so far free that all resistance is at an end, and it comes out as easily as if broken inside, as Dr. Mundé thought it was in his first case. As soon as it begins to peel out, and without drawing it out further, I cover the wound with a clean sponge and operate on the other side. I always stand on the side opposite to that on which I am operating, thus getting a better view into the canal, and draw the ligament more conveniently towards me. Having freed the opposite ligament, the difficulties of the operation are at an end, and the second stage is finished. The structures mistaken in the earlier operations for the ligament were bands of fascia, the nerve and especially fasciculi of the internal oblique muscle. The latter are very like it, are very brittle, and I have no doubt have been the "frail fatty degenerated ligaments" some operators have found and been unable to pull out. They seem to go along the canal in the direction of the ligaments. They should never be seen when the operation is satisfactorily performed.

The third stage consists in placing the uterus in position with the sound, and pulling out the ligaments until they are felt to control that position. A third assistant first replaces the uterus and holds it in position. The operator then pulls out both ligaments almost simultaneously and gently until the sound is felt to be slightly moved. Both ligaments are then held by an assistant, and the operator, with curved needle and moderately fine catgut, stitches each to both pillars of the ring by two sutures on each side. The assistant then lets go, the chafed ends of the ligaments are cut off, and the re-

mainder stitched into the wounds by means of the sutures that close the wounds. A fine drainage tube is inserted, and the wound washed out with antiseptic lotion before these last sutures are tied. In private I do not use the carbolic spray, but in every case use drainage, and never allow patients out of bed under three weeks. In cases of retroversion and prolapse I insert, before the dressing is applied, a Hodge's pessary, and keep it in at least during the convalescence. To counteract retroflexion a galvanic stem should be used for at least a month.

The most important point in the third stage of the operation is to get the right tension on the ligaments, which is, after a little experience, easily gauged by the check of the weight of the uterus.

The after-treatment consists in rest. The wound is dressed and the tube removed on the second day. Patients should not be allowed up for three weeks, and rest on sofa for a further period is decidedly advantageous.

As to results, 3½ years' experience seems to point that the danger of mortality is *nil*, whilst the operation is an absolutely certain cure for retroversion and retroflexion, also very successful for prolapses.

### SOME POINTS IN THE TREATMENT OF UTERINE FIBRO-MYOMATA. (a)

By THOMAS MORE MADDEN, M.D., F.R.C.S.E.,  
Obstetric Physician Mater Misericordias Hospital, Physician to the Hospital for Sick Children, Dublin, Consulting Gynecologist Dublin Provident Infirmary, formerly Examiner in Obstetric Medicine and Gynecology Queen's University in Ireland, Vice-President British Gynecological Society, Consultant National Lying in Hospital, &c.

(Continued from page 25.)

I MAY NOW refer briefly to the alternative operations which, according to my experience, may be substituted for the procedures just discussed. First, then, with regard to *Enucleation*. This operation, although usually restricted to submucous tumours, is, in my opinion, applicable to all fibro-myomata, whether submucous or more deeply imbedded in the uterine parenchyma, which, from the position and size of the neoplasm, are accessible and capable of extraction *per vias naturales*. If this view should be accepted, it would obviously provide an alternative and, as I believe, a generally safer operation in many of the cases in which hysterectomy and other intra-peritoneal operations are now advocated. Every myoma is, primarily histologically undistinguishable from the uterine structure in which it originates, and is only converted into a fibro-myoma or fibroid by the gradual development of its connective or fibrous tissue. Before this process is accomplished—and we are seldom consulted sooner—the tumour also, as a general rule (to which, however, there are exceptions), becomes encapsuled, or distinctly separated by an intervening layer of cellular tissue from the uterine parenchyma in which, as already said, it originated, and from which, however deeply imbedded, it can in most cases be shelled out and removed, or enucleated.

The operation by which this may be accomplished is, at least when performed by those who, like myself, are practically familiar with its details, a comparatively simple matter. In the first place, as for *écrasement* the cervical canal must be previously dilated, the patient placed in a semi-prone lateral position and etherised. Next, the uterus should be washed out with a warm carbolic solution, so as to diminish its vascularity as well as to render it as far aseptic as possible. Then a free incision may be made through the endo-uterine mucous membrane and capsule into the most prominent part of the tumour. This is now seized with a strong vulsellum, by which firm traction is made downwards in the direction of the pelvic outlet, whilst, at the same time, with the operator's finger, or where this cannot reach then with either a curved silver spatula or with Thomas's

spoon forceps, all adhesions around the tumour are broken up. Lastly, the fibroid, by traction with the vulsellum from below, aided by firm pressure from above, is forced out of its bed and extracted either with the forceps or by splitting into sections that may readily pass through the vulvar outlet. By this operation I have removed not only large submucous fibro-myomas but also interstitial, or in some instances partially subserous, tumours. As, however, the feasibility of this procedure in the treatment of any deep-seated mural or partially subperitoneal fibroid is not generally recognised, I may here cite a couple of the many instances of this kind which have come under my care in proof of the occasional curability of such cases even without either abdominal section or vaginal hysterectomy.

CASE I.—*Intra-mural Fibro-myoma removed by Enucleation.*

L. B., an anæmic-looking woman, set. 38, unmarried, suffering from metrorrhagia, pelvic pain, and hæmorrhage, was admitted to St. Elizabeth's ward. Until two years previously she had been in good health. She then commenced to suffer from menorrhagia, which gradually increased, and the intervals between the recurrence of the discharge became so diminished that for the past year she has seldom been a week free from hæmorrhage. On examination, the uterus was found retroverted by a tumour in the posterior wall, and the uterine cavity greatly elongated. The cervical canal was dilated by laminaria bougies, on the removal of which she was etherised, and a submucous tumour discovered occupying the posterior wall from the fundus to near the cervix, and bulging out into the uterine cavity. A free longitudinal incision was made through the thinned muscular structure into the capsule of the tumour, which was firmly seized with a strong vulsellum and drawn down by Dr. Kennedy towards the outlet, whilst with my finger I rapidly separated the loose adhesions around and behind the tumour. This was now forced out of its bed and extracted per vaginam. Immediately afterwards a hot carbolised water injection was thrown up to arrest the free oozing, a tampon of Lawson's cotton saturated in carbolised glycerine was introduced, and an anodyne suppository placed in the rectum. The hot water injection was continued daily for the next ten days, at the end of which the uterus, being still large, was brushed out at intervals with iodised glycerine until it had nearly regained its normal size, and three weeks after the operation she was enabled to leave the hospital.

CASE II.—An unmarried woman, set. 38, who, until the day of her reception into the hospital, had been able to follow her avocation as cook in a large hotel, was admitted under my care. For the preceding two years she had been complaining of continual pain in the back and sense of pelvic weight, debility, leucorrhœa, and slight menorrhagia. These symptoms had gradually increased, but at no time was the menorrhagia very urgent, the changes merely lasting five or six days, and returning every three weeks; nor was there any hæmorrhagic discharge in the interval. On admission her chief suffering was from distressing dysuria—so great that she had been obliged for some time to visit a medical practitioner every day to have a catheter passed. She also suffered from frequently-repeated and generally futile calls to defæcation. She had in addition to tenesmus slight prolapsus ani. Her feet and legs were œdematous, and she complained of great pain along the course of left sciatic nerve.

The vagina was small and the hymen unruptured. On recto-vaginal examination the uterus was apparently completely retroflexed, the hollow of the sacrum being occupied by a large globular tumour extending up as high as the finger could reach, and pressing downwards into Douglas's space. On examination with the sound which passed in upwards of six inches anteriorly, it was evident that the double compression of the rectum and neck of the bladder were caused by a uterine tumour.

To discover the position of this growth the cervix was packed with five sea-tangle tents. On the removal of these next morning the uterine cavity was fully laid open, and as the tumour was interstitial, it was necessary to dissect it out from the posterior wall, in which it was situated, and where it had developed outwards, so as to have become in great measure subperitoneal, the posterior surface of the growth being merely covered by a thin capsule of the uterine structure. In the separation of the tumour, which was as large as the foetal head at the seventh month, the cervical tissue, which had become disorganised by the pressure of the morbid growth, and was, as usual in such cases, extremely soft and friable, was unavoidably lacerated. This rent extended downwards and backwards through the outstretched roof of the posterior vaginal *cul-de-sac*, and left a wide opening into the abdominal cavity. As soon as the tumour, which was as large as the foetal head at the seventh month, was extricated by the midwifery forceps, a coil of intestine came down into the vagina. This was immediately returned, and the patient being then in such a condition of collapse that no attempt could be made to close the laceration by sutures, it was merely plugged with a large sponge, so as to prevent for the moment any further prolapse of the intestines. A drachm of ether was injected hypodermically, and a little brandy and tincture of opium thrown into the rectum. Her pulse, which had been almost imperceptible, became a little stronger, and she was removed to bed and there surrounded with hot jars, &c., with the faintest hope of reaction. This, however, took place, and a couple of hours later her pulse was fairly recognisable, and her aspect improved.

On the second day severe metro-peritonitis set in, and for seven or eight days afterwards her life hung in the balance. It is needless here to dwell on the treatment pursued, which consisted mainly of opium and small doses of mercury, hydrocyanic acid draughts, &c., with the usual local applications—namely, leeching on two occasions, and continual use of fomentations or anodyne poultices to the abdomen, together with warm antiseptic vaginal injections. The vagina was plugged with sponges wrung out of weak carbolic solution. The daily changes of these were effected under carbolic spray, an atmosphere of which was maintained about her. For some days she suffered from incessant retching and hicough, which were controlled by hydrocyanic acid and ice. By the mouth she was only allowed iced champagne in very homœopathic doses, her nourishment for ten days being enemata of beef extract with a little brandy and arrow-root. It is unnecessary to follow the daily notes of the case further than to say that after the subsidence of the peritonitis, from which she was not free for many days, it was found requisite to continue the vaginal plugging for another week, when sufficient adhesion was formed to allow its discontinuance. After the operation her bowels were kept confined for as long as possible. At the end of three weeks she was able to sit up, and a week later was sent to the Convalescent Home at Stillorgan, whence she returned to her former occupation, and is now again employed at the hotel from which she was sent to the hospital.

It is hardly necessary to observe that the enucleation of any fibroid, especially of one deeply intra-mural, is never devoid of considerable danger. But this danger is, I believe, generally less than that of any other of the operations which are sanctioned for the same purpose. The risks of enucleation are, firstly, that as happened in the case referred to, the tumour may have so thinned out the uterine wall behind it that this may be ruptured during the operation, and thus cause immediate death from shock or hæmorrhage, or subsequently from metro-peritonitis or septicæmia. Even where the integrity of the uterine wall was not affected, I have seen death from the latter cause follow the enucleation of a large fibroid.

Hence, it would be impossible to lay too much stress

on the necessity of strict antiseptics, not only during the operation itself, which should always be Listerian, but also in the after treatment by carbolic injections, &c., until the uterine wound has become sealed. Nor, in my opinion, should the operation be ever undertaken by any surgeon who does not believe in the efficacy of the antiseptic system, and who has not time and patience for personally carrying out the subsequent treatment of the wounded uterus in accordance therewith.

*Removal by Traction.*—In the case of those deeply imbedded myomas which are not encapsuled, we may, in some instances, succeed in their removal by the operation which has been recommended by Dr. Emmet for this purpose. The object of Dr. Emmet's operation, which he terms "removal by traction," is the immediate conversion of the tumour by tractile force from an intra-uterine or sessile into an intra-uterine peduncleated or polypoidal form by the method exemplified in the following case.

CASE III.—*Interstitial Myoma removed by Emmet's Operation.*

In this case the patient was a multipara, aged forty-two, who had always enjoyed good health until four years before her admission into the hospital. She then began to suffer from menorrhagia, tenesmus, bladder irritation, and bearing-down sensation which increased. At last she was forced to give up her occupation as a farmer's servant. On admission the uterus was completely retroverted, and on endo-uterine exploration a considerable sized tumour was found bulging out into the uterine cavity. This I attempted to remove by enucleation, but on making an incision for this purpose it became obvious that the tumour was not separated by any capsule from the uterine wall, with which it was continuous. Hence, I resolved on trying to effect its removal, if possible, by Dr. Emmet's traction operation. For this purpose the most prominent portion of the tumour was firmly grasped by a vulsellum and forcibly dragged down through the os as far as possible into the vagina. Here as much of the growth as could be reached was cut away with a strong curved scissors. The resulting hæmorrhage was checked by hot water injections, and the remaining portion of the tumour again similarly treated. In this way we had removed more than two-thirds of the growth, when the patient became so collapsed that I was reluctantly obliged to postpone its complete ablation. A hypodermic injection of ether was administered, and she was put back to bed. For the two days following her condition was apparently satisfactory, her pulse fairly good, and temperature not rising above 100 deg. On the second night after the operation she again became collapsed, and, despite the efforts made to save her, she sank, and died.

In discussing the surgical treatment of fibromata I have confined myself to abdominal operations and their alternatives, and hence I have not here alluded to the treatment of intra-uterine or polypoidal submucous tumours by écrasement, &c.

*Medical Treatment of Myomata.*—With reference to the medical treatment of uterine tumours a few words may be added, chiefly applicable to the cases of non-encapsuled myomatous growths, in which alone medical treatment may be expected to be of much utility.

In many instances, especially of submucous myomata, operative interference is not as essential as is generally supposed. In other cases surgical treatment will not be submitted to, or may not be feasible. And under such circumstances we may, as I have learned by my own experience, sometimes succeed in arresting the progress of the neoplasm, alleviating its symptoms and restoring the patient to comparative health and comfort by purely medical means.

The objects of this treatment are twofold. The first indication is the arrest of that hyperæmic condition which invariably accompanies the development of a fibromyoma, and by which the vitality of the neoplasm is

sustained, and whence originates the consequent uterine hæmorrhage.

The most prominent symptom of fibromata, especially if submucous, and occurring before the menopause, being uterine hæmorrhage, the arrest of this must be a primary object of treatment. For this purpose the patient should be kept at perfect rest from the time when the recurrence of the hæmorrhage is expected until the menstrual period has completely passed over. In the way of medicine, sulphuric acid with liquor ergotæ, or Dover's powder and gallic acid, may be given, or hazeline may be tried. In any serious case of hæmorrhage thus caused, however, it will be better at once to resort to the most reliable styptic remedy for such cases, namely, the free hypodermic use of either ergotine, or, preferably, of the ordinary B.P. liquor ergotæ. During the past eight years I have employed either liquor ergotæ or ergotine in this way in nearly every case of this kind treated in my gynecological wards, and I have no hesitation in saying that we may thus control any hæmorrhage, however extensive, caused by uterine fibromyoma. Moreover, by the continued employment of these hypodermic injections in some instances such a marked diminution in the size of the tumour may be occasioned as to render any further treatment unnecessary.

Amongst the means by which the congestive hypertrophy or general areolar hyperplasia of the uterus, always attending the development of these fibromyomas, may be diminished, and thus the consequent hæmorrhage resulting therefrom can be lessened or checked, none are so invariably beneficial as the persistent and judicious use of hot water uterine irrigations or injections. To be of any use, however, in such cases, the cervical canal must be previously dilated, and the irrigation persistently employed, not only at regular intervals, but also for a lengthened period on each occasion.

Our second therapeutic aim in such cases should be so to stimulate the activity of the local absorbents as, if possible, to induce the diminution of the tumour. Foremost amongst the remedies available for these purposes are iodide of potassium, the bromides of ammonium and potassium, and small doses of tincture of iodine which I suggested ten years ago in a paper on this subject in the "Dublin Obstetrical Transactions." Chloride of calcium, in the form of the old solution of the hydrochlorate of lime of the Dublin Pharmacopœia, from which, in the hands of the late Dr. McClintock, I have seen marked benefit in the treatment of uterine tumours, has again come into favour in such cases, and probably acts by inducing a certain amount of calcification, and consequently diminished vitality in the neoplasm. By far the most useful, however, of all drugs in such cases is iodide of potassium, given in as large doses and for as long a period as it can be safely administered. I have had so many proofs of the diminution in size thus caused in large myomata, in patients of otherwise robust constitution, that I can only account for its failure in the hands of other practitioners from its injudicious administration in the case of patients of broken-down constitution, or in cases otherwise unsuitable, or from the insufficient doses in which it has been given.

Lastly, a word may be added with reference to the benefit derivable in many cases of fibromyomata from the use of iodated and bromated mineral waters. On this subject I have elsewhere written so fully that I shall merely reiterate the opinion, founded on my own experience of spas, which has been without any acknowledgment borrowed by others, and which was gained by extensive personal observation of the effect of the mineral springs of this class in Germany, Switzerland, and France, on patients undergoing "the course," as well as in cases in which I have since then prescribed these waters, viz., that in cases of uterine myomata, when, for any reason, operative interference is not available, we may possibly succeed in arresting the further development of the disease by

sending our patient to a suitable iodated or bromated spa such as Kreuznach, Wildegg, or Schinznach.

## HISTORY OF THE PROGRESS OF LARYNGOLOGY FROM THE EARLIEST TIMES TO THE PRESENT.

By GORDON HOLMES, M.D.,

Physician to the Municipal Throat and Ear Infirmary, London;  
Consulting Physician to the Sheffield Ear and Throat Hospital.

Il importe beaucoup de connaître l'histoire de la science à laquelle on s'attache.—*Boerhaave.*

### EPOCH I.—THE PRE-LARYNGOSCOPIC AGE.

FIRST PERIOD.—*From the Earliest Times to the Death of Hippocrates (about 357 B.C.).*

THE sources of modern medical science can most palpably be traced to the Greek family, society, or school of the Asclepiads, who flourished in the island of Kos during the fourth and fifth centuries before the Christian Era. As their name implies, they professed to be descended from the mythical physician, the deified Asclepius, or, as the Romans called him, Æsculapius. From this school emanated numerous medical treatises, of which about sixty have come down to us, mostly of unknown authorship, but popularly ascribed to the most celebrated member of the school, the familiar Hippocrates, said to have been born 460 B.C., and to have lived to the age of 103. This Hippocratic collection of writings is the only record of the medical knowledge of this period, which it seems to represent fully, and hence laryngology begins with such crude notions of the subject as are there set forth. (1)

For the sake of clearness in chronicling each step in advance, it will be convenient to recount this history in each period under four headings, viz., *Anatomy, Physiology, Pathology, and Treatment.*

Before proceeding further, however, a few prefatory remarks as to the first use of the word "larynx" are called for. This word has not been traced to a Sanscrit origin, nor does it occur in the earliest Greek writers extant (Homer and Hesiod, about 800 B.C.), but "pharynx" is found in Homer (2), a term evidently philologically related, and we may conclude, therefore, that "larynx" was also employed at that date (3). In its most primitive use it was probably the popular name for the eminence in front of the neck, which was commonly recognised as having an important connection with the breath, as we are told that the *pancratiastæ* (boxers, wrestlers, &c.), whose vocation is pre-historic, were in the habit of striking their opponents on the larynx, "so that the animal, through its being crushed, might be suffocated as soon as possible" (4). "Larynx" is used only once in the Hippocratic writings, in the treatise "On the Nature of the Bones" (5), which, being little more than a summary of some of the others, is probably latest in date. The first written appearance of the word is almost certainly, therefore, in a comedy of Aristophanes ["The Knights" (6)], first exhibited on the Athenian stage in 425 B.C. Here the allusion is to holding a person suspended by the larynx as a punishment for certain reprehensible utterances, an indication both of the *pomum Adami* and its relation to speech.

*Anatomy.*—The anatomical knowledge of the Asclepiads was very limited; they may have dissected the lower animals, or perhaps only observed their internal parts in the shambles or at sacrifices. They had but a superficial objective acquaintance with the organs of the body, and had never traced the course of the muscles, blood-vessels, or nerves, and even ignored the connection of the latter with the brain. The windpipe is mentioned by them as the *bronchus* (7), *artery* (8), *tube or artery of the lungs* (9), and *larynx* (10), but its structure is not described, nor is the larynx distinguished from the rest of it. "The larynx," it is stated, "leads to the lungs, artery, and hence to the top of the bladder" (11). The epiglottis, however, had been observed as forming a cover for the windpipe, and is once referred to as resembling an ivy leaf (12), and at another time by its own name (13), which it received on account of

its position on the tongue. There is no description whatever of the cartilages or other parts of the larynx.

*Physiology.*—Physiological knowledge was as scanty as that of anatomy, the brain, for example, being classed as a gland (14), whilst the use even of the muscles was scarcely understood (15). As regards the windpipe, the general belief was that drink passed by it into the lungs. None of the Hippocratic writers, however, appear to have been imbued with this notion; on the contrary, arguments are often put forth to refute such an erroneous idea. Thus, one observer (16) remarks that the epiglottis prevents much fluid getting into the windpipe, and notices that cough is excited should any considerable quantity pass that way. He even demonstrates his case by showing that if for experiment a blue-tinted liquid be given a pig to drink, and the animal is afterwards killed, the bulk of the fluid will be found in the stomach, and only a slight colouration inside the windpipe. And in another place (17) it is stated: "Some persons say that drink is borne into the lungs, and thence into the rest of the body, founding their argument on the fact that the lung is hollow and that a tube is joined to it. But were the lung not hollow and the pipe affixed to it, animals would emit no voice; for we send forth voice from the lung because it is hollow and has also a tube, whilst the lips and tongue render voice articulate." The writer then goes on to enumerate seven reasons why drink cannot enter the lungs, and to prove its passage to the stomach, ending as follows:—"Hence drink is not borne to the lung but to the stomach, for closely joined to it is the gullet of man, which always gapes, and whither the drink tends, whilst a body like an ivy leaf is so related to the lung tube that if in swallowing any fluid should be carried in that direction, a very small quantity is allowed to pass down."

Of the vocal and respiratory action of the larynx the Asclepiads had not the least conception. They were but little in advance of the vague illusions to voice-production in the passage just quoted. Their most definite ideas on vocal physiology are, however, displayed in the following statements (18):—"The cause of speech in man is that the who's body draws the air into it, but chiefly into the cavities. The air being driven out through the empty space makes a noise, for the head resounds. As the air is enclosed in the pharynx, the tongue forms it by its impulse, and by impinging against the palate and teeth, renders it (the sound) clear. Did not the tongue form it by its impulse, man would not speak clearly, but each animal would emit a single sound according to its nature. The proof of which is that those mute from birth cannot speak distinctly, but give forth a single sound. Nor, indeed, if anyone tries to speak after discharging his breath, can he do it, as follows from what has been said? Those who wish to send forth a loud voice, having drawn in the air, expel it outwards, and as long as the air lasts they emit a loud voice, which afterwards is wanting (exemplified by players on the kithara, who sing and vociferate) . . . Hence it is manifest that air produces voice. I have seen, moreover, those who, having cut their throat, had completely severed the whole windpipe. These, though alive indeed, emit no voice, unless someone presses together the throat, and then at last they give forth voice. In addition, this makes it plain that when the top of the throat is cut, the air cannot be drawn into the internal cavities, but is carried outward through the severed part."

*Pathology.*—With such incomplete knowledge of anatomy and physiology, the Asclepiads could not, of course, be in possession of any science deserving the name of laryngeal pathology, but nevertheless they often observed diseases of the throat, as well as of other parts, in an empirical manner with considerable exactitude. The state of the voice in disease was made a subject of special attention by Hippocrates and his colleagues, and its clearness, hoarseness, gravity, shrillness, and failure are often referred to as furnishing important diagnostic and prognostic information (19). The observations of this faculty were, however, of a purely aural nature, and no conception of the part due to the larynx in such phenomena influenced the deductions drawn.

Before the time of the Asclepiads, all inflammations of the throat and neck were designated by the single term *cynanche* (20), but at the period we are dealing with this name was reserved for internal cases, and the modification *para-cynanche* was used when the parts outside the pharynx and windpipe were inflamed. Various forms of *cynanche*

are well described, the chief distinction being between those instances where the disease is obvious in the pharynx and when it affects the parts out of sight below. As there are many writers, we have several pathological observations relating to the same maladies. The etiological conception of cynanche from the pen of Hippocrates (21) himself is that it occurs "in winter or spring when a copious and tardy flow takes place from the head to the jugular veins, which attract it on account of their size. But being cold and viscid, it obstructs, and closing the ways of the breath and blood, condenses the proximate blood and renders it immobile and stable." Again, in the same treatise, it is stated more fully:—"In the summer or autumn a hot and nitrous flux from the head occurs . . . which eates, ulcerates, and fills the breath. There is an accession of breathing with the neck erect and with much dryness. The parts seen in the mouth appear slender, and the posterior tendons of the neck are tense, seeming to be seized by a distention of the nerves. The voice is abrupt, the breathing small, and inspiration frequent and violent. In such cases the artery (windpipe) is ulcerated, the lung is engorged, nor is it able to admit the external air. And unless there be a spontaneous efflux to the outside of the neck, the affection becomes more grave and inevitable." Here we have a picture very suggestive of acute phlegmonous laryngitis, but on what grounds the ulceration of the windpipe was assumed is left to the reader's imagination. It was probably inferred, however, from the character of the sputa, which, as shown in other passages (22), were carefully examined.

Another writer (23) in the collection makes three forms of cynanche, the first of which is an acute laryngitis more severe than the usual catarrhal form, probably oedematous. The two latter are generally confined to the pharynx, but may extend downwards to the lungs. He says:—"The patient is taken with fever and rigor; there is headache, and the jaws swell. He swallows his sputa with difficulty, and makes a noise at the bottom of the pharynx. On observation after depressing the tongue you will see that the uvula is not swollen, but soft. The pharynx is filled with viscid saliva, nor is the patient able to spit out nor to remain recumbent, for if he lies down he suffocates. . . . The disease is of a fatal nature and but few escape."

A third author (24) describes as cynanche a severe acute inflammation, mainly, as it seems, of the windpipe, but frequently involving simultaneously the neck and fauces. It is said that "the patient's eyes start from his head, all his senses being dulled, reason even being lost, nor does he say, hear, or do anything, but lies with his mouth yawning and the saliva pouring forth. In this way he dies on the fifth, seventh, or ninth day."

As paracynanche the same author treats of a lighter form of the disease, in which the most fatal symptoms are absent, so that recovery is likely.

Elsewhere (25) it is stated as a definition that "cases of cynanche with nothing evident in the neck or fauces, but which bring great dyspnoea, kill on the same or third day."

Respecting chronic and ulcerative affections of the windpipe there are also some suggestive descriptions and allusions. Three or four kinds of phthisis are described, in one of which it is particularly noted that "the voice is clear and emitted without pain;" but, in another form the malady pictured closely resembles laryngeal phthisis, syphilis, or cancer (26), *e.g.*, "The lung-pipe is suffering with a hot and superficial ulcer, a slight fever urges, pain in the middle of the chest vexes, and itching of the whole body. The voice is coarse, the patient spits a liquid and thin sputum, sometimes like the juice of pisan. In his mouth a heavy odour, such as proceeds from fish, arises. Repeatedly there appears matter in the sputalike frustules of fungus from the ulcer. The upper members and the whole body are emaciated, the cheeks are red, and the nails in course of time are contracted and become dry and pale from the virus. Presently, however, the patient perishes ejecting blood and pus in the sputa, unless he be cured. Even afterwards vehement fevers supervening kill him." From the same pen we have further observation (27) somewhat similar, viz, "Should the artery be wounded (*i.e.*, from within by ulceration) cough troubles, blood is spit with the cough, the fauces fill with blood imperceptibly, and the patient rejects clots. Acute pain passes from the breast to the back, the sputum is glutinous and copious, the fauces are dry, and fever and rigors attack. The pharynx gives forth a dull and stridulous sound, like fat (frying), and for sixteen days the sick person

is thus affected. Afterwards, however, he spits pus and frustules of the ulcer-like seeds. These are the cartilaginous part of the lung called *bronchia*. Again, there is cough, and blood bursts forth, and after this the sick person spits thick pus. And he is erroneously considered to be one in whose lung an abscess has burst."

The vocal (laryngeal) affection in lepra is referred to (28), and there are allusions (29) to ulcerations of the fauces in children, some of which spread downwards and hinder respiration. Of such ulcers those showing anything of a pellicle are set down as most dangerous.

*Treatment.*—The pharmacopoeia of the *Asclepiadæ* was sufficiently extensive, and treatment was generally rather actively carried out. Bleeding, purging, shaving the head, and fomentation were liberally resorted to in acute diseases.

In the cynanche referred to by Hippocrates (30) he counsels bleeding both from the arms and from the sublingual veins, with purging, hot gargles, shaving the head, and application of ointments thereto and to the neck, wrapping the neck in wool, and then fomenting it with sponges of warm water, with hydromel internally, and emollient drinks.

The second writer (31) omits the bleeding, but a blister to the back of the neck is recommended, apparently as a substitute. In addition to gargles, fomentations, and emollients, he prescribes inhalation through a tube of the vapour from vinegar in which nitre, origanon, and nasturtium seeds have been steeped.

In the form called paracynanche (32) bleeding from under the manubria is strongly advised (because "the breath from the lungs is hot") as well as from the sublingual and brachial veins. Inhalation of a mixture of Cilician hyssop, sulphur, and bitumen through a tube, especially by the nose, is also prescribed. A curious measure is further mentioned which has been thought by some to refer to cutting open the windpipe, viz., "A tube is to be passed into the pharynx by the jaws, through which the breath may be drawn into the lung; it should be seen that the patient spits as quickly as possible, and the lung is to be expanded (made thin.)" (33)

In the first instance of ulceration (34) we are desired to give an emetic (decoction of lentils with white hellebore [*veratrum*]) moderated in potency according to the strength of the patient. Purging is to be avoided, except in cases of pronounced fever, but asses' milk is to be taken as a laxative, or to be administered in enema should the patient be too weak to drink it in quantity. When the sputa are very copious sternutatories are to be used, but ordinarily expectorants only, also fumigations in the presence of a bad odour. In addition a carefully regulated diet (of mutton, fish, bread, &c.), with general hygienic methods, abstention from all excesses, and gentle out-door exercise are ordered. In the second case (35) the only special treatment advised is cauterisation of the chest, back, and front, so that ulcers may be formed; beside avoidance of fatigue, carriage exercise and regular living.

(1) Among the earliest medical works extant are the Sanscrit *Shastres*, or commentaries of Charaka and Susruta on the "Ayr Veda" (life or health knowledge), a collection of rules mythically ascribed to Dhanvantari, the Hindoo Esculapius. The work of Susruta has been translated into Latin by F. Hessler (Erlangen, 1844). It dates from about 1400 B.C., and contains some vague descriptions of throat diseases, but nothing suggesting any knowledge of the larynx. Speaking of ancient Hindoo medicine, T. A. Wise, M.D. ("History of Medicine," 1-67, vol. 1, p. 135), states: "The scanty knowledge of anatomy is likewise evident from the Hindoos employing the word *khant* to designate the throat, including both the trachea and oesophagus, and the term *kules* with the Hindoos expresses the heart, liver, spleen, and stomach. This vagueness extends to the diseases of the organs," &c. The Ebers Papyrus (Leipzig, 1875), an Egyptian medical treatise of about 1600 B.C., appears to contain no allusion to throat diseases.

(2) *Odyssey*, ix., 373.

(3) *Pharynx* and *larynx* evidently mean something like food-way and breath-way, or perhaps are analogous to the German *Schwindkopf* and *Kehlkopf*.

## Clinical Records.

### CLINICAL NOTES IN GENERAL PRACTICE.

#### Note I.—Lithiasis (?)

By JOHN W. MARTIN, M.D.,  
Sheffield.

ON the 18th day of May I was asked to see Mrs. T—, æt. about 36. She had been quite well up to dinner time the preceding day. Her history is one of gouty tendencies, having had a developed attack in the left foot, and on several occasions uneasiness in the knuckles of the left hand. On the 11th, after dinner, she was attacked by an acute pain just below the inferior angle of the right scapula. Being near the onset of the menstrual period she thought it might be connected with it. She usually suffers a good deal at such times in the hypogastric region. No pains felt there on this occasion. There did not appear to have been any irregularity of diet. Thinking that the pain would pass away, she did nothing to obtain relief. On the next day, the 18th, finding that the pain grew worse instead of better, she sent for me. When seen, she seemed most miserable and depressed, the pain being very severe. It was confined to the part described, and was relieved by pressure. There was no soreness or tenderness about the part. She was able to take a deep breath without increasing the pain. The skin was cool. Temperature, 98.4; pulse, 88, and weak. There was no cough, or expectoration. The tongue was coated with a bilious looking fur. She had experienced a sense of distension about the stomach, and had rifted up some wind. There was no pain in the stomach or bowels, the latter were inclined to be constipated. The water was passed in fair quantity, it was high coloured, and inclined to deposit, becoming cloudy on standing. The menstrual flow had appeared during the night, and one small clot had been discharged, beyond this, however, the discharge was normal.

*Treatment.*—Rest in bed. To be well rubbed with the following liniment:—

- R Sp. am. fort., ℥ij;
- Sp. terebinth, ℥j;
- Ol. dulcis, ℥iiss;
- Ol. bergamoli, ℥viiij;
- Aquæ, ad., ℥iv. M.

"To be used as directed." Hot poultices to be applied every two hours. Milk and beef-tea diet, and the following mixture and pills to be taken:—

- R Pot. bicarb., ℥j;
- Tr. nucis vom., ℥xl;
- Sp. am. aromat., ℥iiss;
- Sp. eth. nit., ℥j;
- Syrupi zingib., ℥iij;
- Aquæ, ad., ℥viiij. M.

℥j. to be taken every four hours.

- R Iridin;
- Enonymin, ʒā, gr. j.;
- Pil. colocynth co., grs. ij.;
- Ext. hyoscyami, gr. j.;
- Ft. pil. mitte, xii. M.

Sig. "Two at bedtime." The pain continuing in the evening, I gave the following night draught:—

- R Chloral hyd., gr. i.;
- Potass bromidi, ℥ij.;
- Liq. morph., ℥ss.;
- Syrupi aurant, ℥j.;
- Aquæ, ad., ℥iij. M.

Half to be taken at 11 o'clock, the rest in an hour's time, if not asleep, or free from pain.

May 19th.—Found my patient much better. Had had a good night, except that about 4 a.m. the pills acted three times, with only a short interval between each motion. The tongue was cleaning rapidly. The pain was much diminished, but still felt. There was no further discharge of clots with the menstrual flow. The pulse was stronger, 76 in the minute. Temperature still normal. Careful percussion and auscultation of the right dorsal surface failed to detect any abnormal condition of the lungs. Hepatic region normal to percussion and palpitation. Felt a desire for other food than the beef-tea and milk. I allowed a poached egg on toast, as an addition to diet; continued the mixture; stopped the poultices, replacing them by sheet cotton wadding, the rubbing being continued. Still confined her to bed.

20th.—Much better. The pain very slight, and diminish ing. Tongue quite clean. Felt a healthy desire for food. Pulse and temperature normal. Skin quite cool. General appearance and spirits greatly improved. The bowels had been moved again three times after my visit on the previous day, six motions in all. Allowed meat to dinner, also allowed her to get up in the afternoon, and for the evening. The other treatment to be continued.

22nd.—Felt almost well. Tongue clean. The appetite good. The expression of pain and distress had quite passed from her face. She felt able to move about freely, and when her attention was engaged she felt no pain. When not occupied, and she had time to think about it, she occasionally felt short sharp returns of the pain; she herself was inclined to regard them as neuralgic.

26th.—Since last visit on Sunday, the 24th, the water was again very thick, and deposited lithates very freely. The pain returned very severely, and she felt thoroughly disheartened and depressed. The same evening, and on Monday, at bed-time, she took one of the pills, they acted mildly, and gave great relief. To-day she felt all right, only traces of the pain. The water is again quite clear, and is passed in good quantity. The tongue presented a clean and normal appearance, and her appetite was good. I ordered the following mixture, and discontinued further attendance:—

- R Potass bicarb., ℥j.;
- Tr. nucis vom., ℥xl.;
- Sp. am. aromat., ℥iiss.;
- Infusi gent. co., ℥viiij. Ad. M:

℥j. three times a day between meals.

*Remarks.*—There is nothing very remarkable in the foregoing case, it presents, however, in an interesting form, a picture of some of the difficulties which meet the general practitioner in the routine of his practice. The history of gout and gouty tendencies of course first attract attention, confirmed by the fact of lithic deposits in the urine. With such a constitutional foundation, there would have been no difficulty in accounting for the pain as purely neuralgic, dependent upon the state of lithiasis, but one was compelled to take into account the dyspeptic symptoms, the constipation, and the onset of the catamenia, especially when, with the latter, there was the discharge of a clot. One had to make choice, in giving one's opinion in answer to the straight question "What is it, Doctor?" from, 1st. Was the pain due simply to dyspepsia? 2nd. Was it purely neuralgic, gouty in its nature? 3rd. Was it reflex disturbance due to the onset of the menses, together with the attempts on the part of the womb to discharge the clot? 4th. Had the constitutional disturbance of the approaching menstrual period set up the gastric symptoms and acute lithiasis? The public generally do not appreciate the refinements of diagnosis. They want a name putting to whatever may be the matter, and one which they can readily grasp and understand; that is just what it is difficult to do in the class of cases of which the present record is a fair example. One's tact in hedging, and the use of general terms, is called into play. There is one consolation, and it is, that the proper treatment is not a matter difficult to decide upon, and in the majority of cases is likely to be attended by the same success as in the present instance.

ACADEMY OF MEDICINE IN IRELAND.

MEDICAL SECTION.

MEETING HELD FRIDAY, MAY 1ST.

The President, Dr. CRUISE, in the Chair.

### THE FORM OF PNEUMONIA NOW PREVALENT IN DUBLIN.

DR. JAMES LITTLE detailed thirteen cases of pneumonia which he had seen in private during the past winter; of these eight had proved fatal; and the author drew attention to the frequency with which pneumonia, as at present epidemic, was accompanied by grave complications. He then invited discussion on the treatment of the disease, and specially on the question whether quinine exercised any beneficial influence.

DR. J. W. MOORE, discussing the ætiology of the disease from his experience at Cork Street Fever Hospital, considered the treatment of acute pneumonia was very little more within the grasp of the physician than the treatment either of typhus fever or of enteric fever. That treatment resolved itself into dealing with symptoms as they arose, each of which may threaten life. Statistics indicated that acute pneumonia had been very prevalent in Dublin, and, as Dr. Little had observed, the mortality of the present epidemic was exceedingly high. Thus, of 101 cases treated in Cork Street Hospital during the twelve months ending March 31, 1885, 24 died, or very nearly 24 per cent. It was interesting to note the increase and decrease in the admissions according to the season, the majority of cases being invariably admitted in the months of April, May, and June inclusive, not in the coldest season, but during the period of transition from the damp cold of winter to the dry cold of spring and early summer. Another feature of interest was the remarkable correlation between acute pneumonia and enteric fever. During the winter he saw three cases in which the diagnosis of croupous pneumonia was unequivocal, and yet when the time for resolution of the lung came the fever ran on, and the cases turned out to be typical instances of enteric fever, with rose spots, &c. In reference to the instance given by Dr. Little of more than one case of pneumonia occurring in the same house, Dr. Walter Smith communicated recently a still more remarkable instance in which four cases of pneumonia occurred under the same roof. Similar instances were increasing in frequency. Some years ago a young lad was admitted from a house in Malpas Street, suffering from croupous pneumonia. Three weeks afterwards the father came in with the same disease. In his opinion acute pneumonia was an essential or specific fever, analogous in its origin to enteric fever. How, then, did the disease break out after exposure to cold or chill? Bearing in mind that the poison was determined towards the lungs, there was an additional exposure to the poison of the disease, and the receptivity of the patient was increased. They could not hope to stop the course of a typhus fever, nor could they stop the course of this specific fever, which tended to a crisis at the conclusion of six or seven days. The sequelæ mentioned by Dr. Little as following pneumonia afforded further proof of its specific character.

DR. FITZPATRICK recollected, half a century ago, seeing cases in the Meath Hospital treated by the late Dr. Stokes with tartar emetic. In Edinburgh, at the same period, the treatment was on a different principle, consisting of small doses of calomel, opium, leeching, and cupping. On returning again to the Meath he found the treatment had been changed. In explanation, Dr. Stokes said his theory was that, since the invasion of cholera, the public constitution had changed, and that patients would not bear the same treatment as in former days. He had himself had under treatment four cases of croupous pneumonia among the children of one family. His treatment comprised chlorate of potassium and bark and blisters—indeed, he attached the greatest importance to blistering as a most efficacious remedy.

DR. DUFFEY considered that physicians were much too chary in giving opium in pulmonary disease. There was a prejudice against it; but any bad results could be averted or kept in check by careful observation of its effects. He had seen good results follow from the careful and regular

administration of opium in cases of croupous pneumonia. Given hypodermically, the pain of pleurisy (which was generally associated with pleuro-pneumonia) was relieved. He had himself been in the habit of using ergot combined with opium. Ergot was a powerful cardiac depressant, besides constricting the blood-vessels. Therefore, in a disease like pneumonia, in which there was a large quantity of blood in the lungs, it diminished the amount going through the pulmonary vessels. Quinine, he submitted, was utterly useless; he never saw the slightest good resulting from it. Poultrices, he thought, did more harm than good, and putting a large poultice round the chest was bad treatment. Aconite ought to be looked upon as a cardiac depressant too.

DR. HENRY KENNEDY spoke of a gentleman, at 54, already alluded to, who, having got a wetting on two days in succession, was ill in bed from Tuesday till Saturday without seeing a doctor. He died after an extraordinary fight for his life, which might have been saved had he obtained advice sooner. On seeing the case, he came to the conclusion that the patient had a weak heart. He agreed with Dr. Duffey that quinine was not generally good treatment. Another medicine was infinitely more useful—namely, a pure stimulant which would agree where quinine would disagree. As the result of his experience, he found that quinine did not equal either wine or whisky. Although the effect of the three was much the same in improving the pulse, yet the strong drink was the better treatment as agreeing better with the patient. He placed reliance on mercury, with which he had treated a number of cases, giving small doses—commonly the blue pill, sometimes even the bichloride of mercury. He had great faith in blistering pneumonic cases, but to be of service the blister should not be an insignificant four-inch one, but the size, say of a page of foolscap paper. That hint he took from Sir Henry Marsh, who said, "If you want to do any good apply a large blister." Poultrices were, in his opinion, quite secondary to other treatment.

DR. MORE MADDEN observed that in the Hospital for Sick Children pneumonia was one of the most common diseases. Within the last few months pneumonia had been unusually prevalent and peculiarly fatal in its character. In one instance he had two and in another three members of the same family suffering from pneumonia—a fact worthy of observation in connection with the epidemic form of pneumonia. Speaking from his fourteen years' experience of pneumonia in that hospital, the different forms of pneumonia occurring in different years required different treatment. He could not agree as to the efficacy of medicine in all febrile diseases. His opinion was that, while fever could not be cut short, it might be guided to a safe termination by medical treatment. Pneumonia was a fever with local complication. The cases he had seen recover had been treated with quinine, and poultrices had been applied. He had found it necessary to give mercury in combination with quinine and other treatment. He believed in the anti-phlogistic power of mercury, and had he the disease himself he would like to be wrapped up in poultrices and be given mercury, quinine, and stimulants.

MR. JOSEPH KENNY observed that in the workhouse hospital of the North Dublin Union there was an extraordinary prevalence of pneumonia. In connection with the outbreak of the disease he noticed, either concurrently or immediately before it, the prevalence of erysipelas. In the present epidemic the disease attacked the left lung with greater frequency than the right, and (contrary to the usual experience) the upper lobes of the lung rather than the base. In young subjects his experience was contrary to Dr. Little's—the mortality was exceedingly low. Dr. Duffey had stated that the application of poultrices was not only of no good, but the opposite. It was doubtless the misapplication of poultrices he meant, for if properly applied poultrices were exceedingly useful. Quinine treatment was what he adopted, but he had combined it with gray powder, and digitalis or ipecacuan, with or without opium, as the case demanded. Blisters followed by poulticing he found to be of great use. Believing as he did that pneumonia was a septic disease, he should regard quinine as a remedy of some value, whereas a man who looked on the disease as the result of cold might not take that view at all.

THE REGISTRAR-GENERAL said that the cases of pneumonia spoken of by the present speakers were of a more severe character than those with which he was familiar

Some years ago he came to the conclusion that pneumonia was essentially a fever, and that too an infective fever.

Surgeon ORMSBY said he had performed venesection in a case of croupous pneumonia at the Meath Hospital with good results.

Dr. HAWTREY BENSON had treated cases with quinine, stimulants, poultices, and blisters.

Dr. FINNY said he had never seen so many cases of pneumonia as within the last six months, and it was different from the pneumonia of former years. A great amount of lung tissue became involved. In ordinary pneumonia the fever ran to a high pitch, the crisis taking place about the eighth day. But in the present epidemic the temperature rarely passed 103°, or from 103° to 104°, and the crisis occurred about the fifth day. Another point of interest was that the disease spread from one lung to another, pleurisy being very common. Acute delirium, such as was seen in typhus, was also a common symptom of the disease. Amongst the physical signs of pneumonia one frequently present was the tympanic resonant note above the attacked portion of the lung, and this was followed by the extension of the disease. His experience differed from Mr. Kenny's—the disease attacked all the lobes indifferently. Statistics seemed to point to the lower lobe, but in the present epidemic the one attacked was just as often the upper lobe. The treatment he adopted was exactly the same as for a severe fever. He treated the patient and not the disease. Adapting the treatment to the suffering of the patient, he gave quinine in moderate doses, and morphia or opium internally, and local relief by cupping and poulticing. Stimulants were also necessary. His attention was directed to strengthening the heart and inducing sleep.

Mr. DOYLE said he had in all cases, for the last three or four years, been in the habit of using local lukewarm packing, which he found relieved the pain quite as effectively as ice-packing did. He would give large doses of quinine once in the twenty-four hours to bring down the temperature. In treating pneumonia the fever must be treated.

Messrs. McCULLAGH and BURGESS having also spoken,

Dr. DUFFY, as a personal explanation, said the point of his remark on the uselessness of poultices was as regards the effect of stopping the disease. He frequently used poultices himself, but he preferred cotton wool.

The PRESIDENT concurred as to the fatality of pneumonia in the present epidemic, especially once the meridian of life was passed. One point escaped attention in the discussion—namely, the presence of pneumonia in renal disease either of a temporary or of a permanent character. It was astonishing how many cases there were of renal disease in those who passed sixty years of age. A number of cases would exhibit albuminuria even when little expected. With regard to treatment, admitting pneumonia to be a fever, the great object must be to keep the patient alive until the crisis arrived on the seventh, eighth, or ninth day. Upon this principle, even without reference to considerable practical experience, he believed in the value of quinine. He believed that quinine was one of the drugs—perhaps the only drug—which in a vast proportion of cases enabled the physician to overtake the disease or enabled the patient to live till the disease subsided. He had seen valuable results from blisters in moderation, and at the stage when the temperature came down and resolution was hanging fire—just about the same time that one would use mercury and iodide of potassium. On the other hand, he had seen terrible evil, even fatal results, ensue from the application of very large blisters in pneumonia. Feeding and stimulants must occupy a prominent place in attending to those cases.

Dr. LITTLE, in replying, was sure that the President was correct in saying that a great number of cases of pneumonia were those of old standing renal disease, and for years past he had himself regarded death as a foregone conclusion in cases of patients attacked with chronic Bright's disease. He could speak in the most confident way as to the value of packing of the chest in croupous or lobar pneumonia. As to blistering, his opinion was in accord with that of the President. Post-mortem examination showed violent pleural inflammation underneath the blister. In an autopsy, where a man had been extensively blistered, he traced the blisters on the pleural membrane in patches of lymph, so that he had a great horror in applying blisters until the temperature had come down. The physician could avert the tendency to death. Leeching or blood-letting averts the tendency to death arising from over-loading of the right side of the

heart. Hypodermic injections of morphia, when the patient was in a state of dyspnoea with intense pain, induced sleep, and contributed to recovery. There were other ways of securing sleep, stopping nervous disturbance, and averting the tendency to death; but with regard to affecting the disease he was in doubt. They should not be led away by speculative considerations. They should not, as Sir James Paget expressed it, be guided by the dim and treacherous ray of speculation, but observe the effects of quinine, or other remedies, unbiassed by theoretical reasoning. He had himself been persuaded by a medical friend to try ergot, but he never saw any good effect from it. For his own part, he had at the outset faith in quinine, then he began to lose it, and now his faith was coming back because in the practice of other physicians the cases did well where the quinine was fairly administered.

The Section then adjourned.

#### BRITISH GYNÆCOLOGICAL SOCIETY. MEETING HELD JUNE 10TH, 1885.

Dr. MEADOWS, President, in the chair.

SPECIMENS were shown by Dr. Smith, Mr. Reeves, and Dr. Bantock.

Dr. ALEXANDER, of Liverpool, then read the paper of the evening, on an operation which bears his name as the originator, entitled

THE OPERATION FOR CORRECTING SOME UTERINE DISPLACEMENTS BY SHORTENING THE ROUND LIGAMENTS, a full abstract of which will be found at page 45.

A brief discussion followed the reading of this paper, in which

Dr. MEADOWS inquired as to the advantage of the "galvanic" stem pessary—that instrument having been very unfortunate in his hands.

Mr. LAWSON TAIT said he had done four cases of the operation, and one had died. He then ceased to perform it, considering the risk to the patient uncompensatory for the advantage possibly attainable.

Mr. REEVES wished to know if half-an-inch skin incision was considered sufficient, also whether Dr. Alexander could before operating diagnose as to the existence of uterine adhesions, and if so, as to their extent.

In reply, Dr. ALEXANDER said the "galvanic" stem was used simply on account of its mechanical convenience, and not for any galvanising properties. In his hands no evil had accompanied its use. To Mr. Tait he must say the patient probably died of some disease, and not the actual operation, and would wish him to try it more extensively. The question of skin incision was one very much for the individual operator to settle, but should never be less than 1½ in. to begin with. Adhesion could in some cases be detected.

### Special Articles.

#### THE ABUSES OF LONDON MEDICAL CHARITIES.

MR. ROBERT FREWER, Secretary of the Hospital Saturday Fund, has recently made a communication to the Metropolitan Provident Medical Association, which lays bare a few of the anomalies and abuses of the London hospital system, and is calculated to inspire us with serious doubt as to the right of some of these institutions to be called charities at all. Mr. Frewer expresses the opinion that there remains a great work to be done before the charitable contributions of departed philanthropists are rescued from the grasp of men and classes for whom they were never intended, and reconsecrated to the grand purposes for which they were given.

"Is it possible to largely increase the work and usefulness of the London Medical Charities without adding to their present income?" I need say no word upon the great importance of this question. It embraces the welfare of the vast aggregate of the sick poor, who in ever-increasing numbers crowd the hospitals and dispensaries of London; and who, I believe in the great majority of instances, are unable to pay the ordinary fee of the family doctor. It is a

fact, and not altogether a pleasant one, that about 1½ millions of the inhabitants of London are annually relieved, while no fewer than 6,000 beds are constantly occupied by in-patients at the various metropolitan hospitals, so that a number equal to the entire population of a town of considerable size are day and night under the ever watchful and loving care of an army of medical men and their helpers.

Perhaps the successful establishment of a complete network of dispensaries, in accordance with the scheme of the Metropolitan Medical Association, would go far towards removing many of the abuses now existing in connection with the out-patient department.

The scheme, says Mr. Frewer, for turning endowed institutions, such as St. Thomas's Hospital and Guy's Hospital, into pay-hospitals, seems to me such a glaring and indefensible perversion of the intention of the founders of these institutions that I cannot suppose such a course will long be tolerated. The doors are open to all who will pay three-pence for advice and medicine, while at both Guy's and St. Thomas's the "well-to-do" are provided with comfortable apartments, advice, and medicine included on reasonable terms, inquiries to be made, &c. I trust that such inquiries will be made as will ascertain whether or not the course now pursued by the governing bodies of these great endowed charities is, or is not, at variance with the terms of the charters under which such charities were established.

I believe the establishment of pay-hospitals to be a good thing, and I believe that the middle classes will readily support such institutions by the payment ungrudgingly of such fees as may be necessary for their support; but I protest that it is wrong for such institutions to accept charitable contributions in any form. Against the proposed conversion of endowed charities into provident institutions I shall always protest in the strongest possible manner.

Now, let us for a few minutes examine the yearly reports of the London charities. I take the reports of seventy-two hospitals and thirty-nine dispensaries, and I find that these institutions received in their last financial year £67,500. Relief was given to 68,500 in-patients and 1,168,000 out-patients. An average of 6,000 beds were occupied during the year; and there were about 4,000,000 attendances of out-patients. An analysis of these figures shows that each attendance of out-patient costs 8½d., and every bed occupied costs per week £1 14s. 4d. Can this be justified? or is it not clear that the existing medical charities might greatly increase their usefulness without adding to their present income?

Taking the largest hospitals whose reports are at hand, I find 1,074 beds always occupied maintained at an average cost of £1 9s. 10d. per week; and 391,749 attendances given during the year costing 7½d. each. At the three smallest hospitals we have a total of 79 beds maintained at a cost of £1 8s. per week, and 127,200 attendances costing 7d. each. The difference is not great, but it is worth notice that, contrary to our general notions of these things, the smaller hospital is the least expensive. How is it that one small hospital, of good repute, but with only 17 beds occupied on an average, is able to maintain each bed at a cost of 25s. per week, while the larger hospitals, having respectively 282 beds and 184 beds, are only able to maintain those beds at a cost of £1 13s. 6d. per bed per week?

Of the special hospitals I dare not trust myself to speak. Some are, doubtless, institutions of great value, and managed in a manner above reproach: but I fail altogether to discover any justification for the varying expenditure and results. The cost per bed ranges from £1 to £5 per week; the cost for attendance of out-patients ranges from 3d. to 4d. to 3s. or 4s.; nothing appearing to justify these great differences. One consumption hospital maintains 30 beds at a cost of £1 7s. each per week; another institution of the same character 19 beds at a cost of £2 10s. per week; a third institution, not long opened for in-patients, has managed to maintain two beds, and attend to the same number of out-patients as the hospital with 30 beds, there being very little difference in the income of the two institutions. Here is an hospital for diseases of the nervous system, having no in-patients but children, every bed appearing to cost about £1 18s. per week. The average cost of beds at the various lying-in hospitals is about £2 10s. per week, while the cost of attendance upon out-patients may be estimated as quite equal to the amount paid to the ordinary practitioner by working people. Generally speaking the expenditure at those institutions devoted to the diseases of

women and children seems excessive, and incapable of satisfactory explanation. It is only right that I should here mention an exception. There is one institution, as efficient in every respect as any to which I am referring—I mean the Royal Hospital for Women and Children, in the Waterloo Road—where an average of 50 beds are maintained at a weekly cost of one guinea each, while 28,000 attendances are given to out-patients, each year, at a cost of 4½d. per attendance. How in the face of this experience can another institution for women and children of the same size, and having the same object, justify an expenditure exceeding £2 2s. per bed per week, and 10d. for every attendance of out-patients?

A glance at the reports of hospitals for children is not re-assuring, and does not relieve one from the impression of mismanagement or extravagance somewhere. Here we find in ten hospitals—especially for children—520 beds occupied and maintained at an average cost per week, exceeding by 6s. per week each bed the cost incurred at such institutions as King's College, or Westminster, or the London Hospitals. We are also startled at the grossly unjustifiable differences of cost shown by these children hospitals. Again, to mention a noteworthy exception—the Alexandra Hospital for Children with Hip Diseases, is able to maintain efficiently, and with every necessary comfort and appliance, 74 beds for children, always occupied, at an expenditure of 12s. weekly each bed; this cost being considerably more than doubled at the five larger children's hospitals. I wholly fail to discover why this difference should exist. The largest children's hospital maintains 10 beds at a cost of £1 9s. 3d. each weekly.

Comparing the annual reports of the dispensaries of London, the differences in costs and results are even more striking. As in the case of hospitals, I take the three largest institutions, and find that 51,360 patients are relieved at a cost of 1s. 2½d. each. The three smallest relieve 3,029 patients at a cost of 2s. 2½d. each. That the small dispensary should be generally speaking more costly than the larger one is perhaps to be explained. But here are two dispensaries, both in the Western district: one relieves 14,000 patients at a cost of £467, and the other relieves 4,000 patients at a cost of £1,165. In one case every patient costs 5s. 7d., in the other 7d. At the larger institution the medical staff and nurses receive £189. At the smaller institution doing less than one-third of the work it is £421; or in other words, at the favoured charity the medical staff and assistants receive 4s. for every patient attended, while at the other they are content with *three pence*. It is not always that the larger dispensary is the most economical. The dispensary with the largest income I find relieves 14,000 patients at a cost of 2s. each; while the dispensary with the smallest income relieves 3,200 patients at a cost of 1s. each.

It is quite time we proceeded to draw some general conclusions. I find that such institutions as King's College, Westminster, the London, and the Metropolitan Free Hospitals are able to maintain every bed occupied at these institutions at a cost of less than 25s. per bed per week, and that every attendance of out-patients costs less than 6d. each. Are there any who would deny the efficiency of these institutions, either as hospitals for the relief of the sick poor, or as schools of medicine? And if the expenditure at such institutions as I have mentioned is sufficient for every possible requirement to maintain these institutions in the highest state of efficiency, why should the *average* cost at the hospitals and dispensaries which we have had under our notice—many of them very inefficient compared with those I have selected as models—why, I ask, should the average reach £1 14s. 4d. weekly for every bed, and why should every bed, and why should every attendance of out-patient cost 8½d.? I do not suggest for a moment that the principal officers at our London medical charities are not over-paid.

If it be possible, as I believe it is, to reduce the average expenditure of these 111 hospitals and dispensaries to that of the hospitals to which I have referred as models of all-round efficiency, there is complete provision, without adding to their present income, for 7,000 beds instead of 6,000 now occupied, and for 5,000,000 attendances yearly instead of the present 4,000,000. Now, how do the figures stand? 7,008 beds at 25s. is £455,000, and 5,000,000 attendances at 6d. is £125,000, making together £580,000. There is still an undisposed balance of £95,000. What shall we

do with it? I have no hesitation in suggesting that this £95,000 should be added to the £30,000 now paid to the medical officers of hospitals and dispensaries. We are all ready to acknowledge that, so far as return for valuable service is concerned, the relation of the doctor to the hospital and dispensary is not satisfactory. We have seen that in some instances the medical staff receive as much as 4s. from each dispensary patient. I find, however, that at 67 hospitals 51,119 in-patients and 610,005 out-patients receive the services of medical men of the highest skill, for which service the sum of £17,834 was paid, nearly 6d. each patient; while at 39 dispensaries 196,609 out-patients were attended to, for which the doctors received about 1s. 3d. each on an average. When we consider the seriousness and difficulty attending many of the cases—indeed, a large proportion of the cases—in the various hospitals, for which the doctor receives on an average about 6d. each, we can hardly wonder at the remonstrances which reach us from the medical world with reference to the ever-increasing claims upon the services of hospital doctors. My suggestion that there are funds available for a large increase of payment for services of the hospital doctor, and which should be so used, is not, I think, an unreasonable one, nor unwarranted by the figures here given.

#### TREATMENT OF CHOLERA.

IN view of the possibility of cholera invading our shores, the best methods of treatment should be carefully considered so that there may be no hesitation, when the time comes, as to what particular line of treatment it will be most advisable to adopt. A very valuable, because a very practical, paper appeared in the *Dublin Journal of Medical Science*, for August, 1884, written by Brigade-Surgeon F. E. McFarland, of the Army Medical Department. In it he reviews four principal methods of treatment which he has seen adopted, and which he has used himself. 1. The calomel and opium treatment. 2. The salt treatment. 3. The belladonna treatment. 4. The permanganate of potassium treatment. The first he condemns, because he thinks it adds greatly to the agony of the disease, and, if it does not hasten the patient to the grave, it does not smooth the passage. He thinks it may be laid down as a rule that opium should never be given once collapse sets in. Of the salt treatment he has nothing very decided to say. He was recommended to try it in two ways—first, the following mixture to be given every half hour or hour according to circumstances, and the intensity of the symptoms:—

R Common salt, ℥ij;  
Bicarbonate of sodium, grs. xxxvj.;  
Chlorate of potassium, grs. x.;  
Water, ℥viij. M.

Second, half an ounce of common salt in a pint of water every half hour or hour.

The first mixture was attended with greater success than the second. The patients take either with avidity. Of this treatment he has heard the doubtful recommendation "that more cases of cholera have recovered with the salt treatment—and more have died—than under any other," and he adds, "I cannot speak more clearly of it." Of the belladonna treatment he speaks favourably, especially as a means of bringing a patient out of collapse and controlling it. He narrates one case in which it was specially useful. Its administration requires careful watching, but he thinks it is worth a trial. Of the permanganate of potassium treatment he speaks in the highest terms. "This is certainly the most successful I have seen. The late Surgeon-Major W. A. White, R.A., employed it always, and it was from him I learned it. I think he first saw it used in Bulgaria. It has many things to recommend it. In the first place, you can carry in a small bottle in your waistcoat pocket sufficient

to treat hundreds of cases, and no other medicine is necessary; in the next it is a pleasant medicine. From beginning to end there is nothing in the treatment to cause apprehension to the patient, or add to their sufferings." To give it, a grain of the *pure salt* must be dissolved in four ounces of pure or distilled water; of the solution, a teaspoonful must be given every ten minutes by the watch until reaction sets in; the medicine is then stopped, and beef-tea given. If the solution becomes discoloured, it must be thrown away and a fresh one prepared. Condy's fluid will not do. The clinical evidence in favour of this method of treatment is very striking. The time which elapses before reaction sets in varies from two to six hours. Whilst taking the permanganate of potassium the patient may drink freely of water, or better still, of warm meal. The dose mentioned is the proper dose; if more is given, it is rejected like everything else. The first symptom relieved is the sickness; then the thirst; then heat returns; purging and cramps cease, and after some hours the kidneys act. Dr. McFarland thinks that it is cruel to withhold drinks from cholera patients. He recommends warm oatmeal and water. He has found bleeding a very useful measure, in one desperate case where he had opened a vein, and, no blood coming at first, he had left the arm unbound, copious bleeding set in, and a severe loss of blood had taken place before he could bind it up, immediate relief was experienced, and the patient turned over on his side, went to sleep, and made an excellent recovery. He thinks where bleeding is practised it fails from not being carried to a sufficient extent. The paper is one that deserves to be kept in view, should this country be so unfortunate as to be invaded by cholera at any time in the present or coming years. So far, there is no thoroughly safe and reliable method of treatment known. During the epidemic in Dublin, in the year 1866, the writer remembers the late Dr. Hudson saying that "the chances of a patient's death or recovery under all forms of treatment about equalled the chances of a coin coming down heads or tails upon being spun into the air."

THE number of students coming forward for their final examinations in the Dublin Colleges is, we understand, almost unprecedented. In the College of Surgeons the examinations under the old system have just been completed, and those under the new sessional system commenced last Monday, and at both series of examinations there were a large number of candidates. At the College of Physicians there have been, we understand, 67 claimants for the licence, but the rejection percentage has been very large.

THE "Hudson" Scholarship, founded in memory of the late Dr. Alfred Hudson, the head Dublin physician and formerly connected with the Adelaide Hospital, Dublin, has this year been awarded to Mr. George T. Revington, M.B. The scholarship consists of a gold medal and £30.

HER MAJESTY THE QUEEN has approved of the Good Service Pension of £100 per annum, vacant by the death of Sir W. Muir, being bestowed upon Surgeon General W. Mackinnon, of the Army Medical Staff, who has seen much active service.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 15, 1885.

### DEGRADATION OF THE PRESS.

It is a subject of great regret that there have been of late very numerous manifestations on the part of lay newspapers showing that, in the race for pecuniary success too little anxiety is exhibited to hold that tone of perfect purity by which alone these great organs of instruction can hope to hold their rightful high position as educators of the people. It seems rather as though proprietors of journals are actuated more by the desire of a money gain than by the wish to inculcate principles of truth and morality, for no opportunity of pushing sales by sensational announcements and catch-penny articles is neglected by a certain section of such publications; while even those which are by common consent regarded as the more respectable among newspapers do not, at times, refuse to adopt the discreditable tactics of their less firmly established contemporaries. The truth of this statement can be verified by reference to events no more remote than those attending the late Egyptian campaigns, during which it was a regular experience to find the contents bills of the daily press blazoning with headings descriptive of "news," not only of the most exaggerated type, but as often as not of the most absolutely untruthful character. Again it needs only the merest excuse, the more disgraceful the better to shock the good feeling of society, for the opportunity of

trading on it to be seized on with avidity by some one or other organ of public opinion. Thus it is still fresh in the memory of many that, on the advent of an unprincipled female quack in London, who, under pretence of delivering physiological lectures to women, communicated to those who attended her receptions descriptions of the most disgraceful character, an evening paper took upon itself to commend this woman as a teacher of young English girls, and advised our daughters and sisters to attend and listen to the lectures she gave. Of what nature these abominable discourses were was sufficiently shown in an account of one of them, which we felt it to be our painful duty at the time to print as a warning to those who might be deceived by the specious advertisements inviting the attendance of the public at them.

The principle of pushing sales at the expense of decency has lately been strikingly illustrated by the *Pall Mall Gazette*, which has by its action attained so great a notoriety that it can scarcely expect to be ever again admitted to the ranks of respectable journalism. The subject of its sickening revelations is that with which the world is familiarised through sensational descriptions of the horrors attending a traffic in young girls, who on attaining the legal age at which they are entitled to give consent to their own violation, are said by the *Pall Mall*, to be ruined in large numbers in London alone, for the gratification of unnatural lust. We do not propose to examine the truth of the statements made in this connection; many of them are, to medical readers, palpably absurd, and many of them too bear too much internal evidence of an excitable imagination to permit their being seriously considered. Doubtless, immorality is rife among all classes and all ages; but in order to expose it we contend, in the interests of the national welfare, that a language of propriety may be made as effectual as the gross method of depicting it which has been adopted by the journal in question. There is no excuse indeed for a mode of procedure that appeals so directly to the appetite for prurient details which exists in our midst; and by thus openly pandering to which an injury is done and an offence committed which will cause an amount of damage to public morality a thousandfold greater than all the criminality which has been trumpeted forth by the writers of the articles we complain of. We presume the object of their appearance will not be satisfied by indoctrinating errand boys, cabmen, and the multitudinous frequenters of the streets into the mysteries they expose; yet these are the classes who during the period of their publication were to be seen on all sides eagerly devouring the nastiness they contained, and clearly enjoying the treat served up to them in language apparently designed for the special delectation of the "masses."

So far as an honest desire to protect the helpless is concerned, we, in common with every right-minded person, will heartily co-operate to secure the desired end; but when this is made the excuse for the production of obscene publications the only ones to derive benefit from which are those responsible for their appearance, we cease to sympathise with so obviously one-sided a movement;

and we trust that exemplary punishment may be awarded to those who have spread contamination broadcast, and stimulated unhealthy feelings and evil thoughts throughout the depraved classes of the community.

We would point out, too, that proceedings taken against the writers and publishers of obscene writings are based only on the fact of an offence against public decency. The matter of truth or otherwise of the incriminated articles does not enter into consideration; the only question involved is, "Is this writing indecent?" and on that alone the verdict of a jury and the decision of a judge will be given. This appears to have been forgotten in the composition of the papers referred to, and a good deal of silly vapouring is indulged in by the editor of the *Pall Mall Gazette* as to the names he will disgrace if prosecution overtakes him. No opportunity for making good his threats would arise out of his trial for uttering indecent articles whatever foundation of truth he may imagine he possesses for his statements; and we consider that public purity demands that the offence he has committed against it should be met by its early vindication at the hands of the law.

In connection with this subject we have seen with a feeling of profound surprise and regret, that our usually careful contemporary, the *British Medical Journal*, has undertaken the defence of the *Pall Mall* performance. We sincerely trust that this is due to an absence of consideration of the interests involved, for it would indeed be sad to think that an organ of the influence the *Journal* possesses can descend to approval of proceedings which must necessarily react with such evil general effects. If seemingly respectable newspapers are to be thus prostituted to the lowest aims, and become diffusers of immoral literature without opposition, then we have indeed striven for years in vain to elevate the health of the people by improving the morals of society. If a leading organ of medical opinion can so lightly throw aside one of the first traditions of the profession, then truly is the outlook black; but we prefer to think our contemporary has erred without thought, and that it is before this awakened to contrition for its offence.

#### CAESAREAN SECTION IN CENTRAL AFRICA.

In a recent article on the postures adopted by women in labour in Central Africa in the *Deutsche Med. Zeitung*, Dr. Breitmann gives a most interesting account of the operation of Cæsarean section, as witnessed by Dr. R. W. Felkin at Kahura. The case was that of a very handsome young negro woman, a healthy primipara, aged 20 years. He entered the hut just at the commencement of the operation, but was not permitted to convince himself of the condition of affairs by examination. By the side of the half-intoxicated patient stood a quantity of banana wine. A bandage of Mbugu, a stiff material made from the bark of a tree, went over the breast, and bound the patient firmly to the bed, another passed over the thighs; an assistant held fast the feet, and another, standing on the right side, held the skin of the abdomen on the stretch. The operator, holding aloft the knife, muttered a prayer. After the completion of the ceremony he thoroughly washed the abdomen of the

woman and his own hands with banana wine, uttered a piercing cry, which was repeated by those standing without, and made an incision from the pubes almost to the umbilicus, and right into the uterus, so that the liquor amni gushed out. Some bleeding vessels were successfully touched with the actual cautery. The operator quickly extracted the child, whilst a second assistant drew the edges of the uterine wound apart and compressed them. After division of the umbilical cord, the child was handed to a woman, the operator laid aside the knife, grasped the uterus and compressed it with both hands with all his might. He then dilated the cervix with two or three fingers, removed the blood-clots and the placenta, while the assistants were busied in arranging the intestines, and especially in preventing any portion getting between the edge of the wound. What bleeding still continued was stopped by the actual cautery, whilst the operator still compressed the uterus until it was firmly contracted. No sutures were inserted. The assistant who had before held the abdominal wall on the stretch grasped the angle of the wound and the whole wound was covered with an herb pad. The bandages were now loosed, the assistant grasped the patient by the arms and turned her over into a position in which the fluid in the abdominal cavity flowed out. She was then brought back into the former position, the herb covering was removed, the edges of the wound were carefully adjusted and fixed with well polished needles, similar to acupuncture needles, and made fast by an encircling thread. A paste prepared from two different roots by chewing was laid over the wound in the place of plaster, over this a previously warmed banana leaf, and the whole fastened on with Mbugu bandage. Up to the moment when the needles were inserted the patient had evinced no expression of pain, and an hour after the operation was in good spirits. The temperature did not rise above 37.5° except during the first night, when it reached 39°. Pulse 108.

Two hours after the operation the child was put to the breast, but after about ten days as the milk stopped it was fed by another woman of the tribe. The first change of dressing was made on the third day, a needle was removed, then more followed on the 5th, and the remainder on the 6th. At every change of dressing fresh "ointment" was put on, and the secretion from the wound removed with a tampon charged with it. The dressing was always solid, and in nine days after the operation the wound was healed and the patient quite well. Beyond the interest which naturally attaches to a case of this nature, it is heightened in the present instance by the quaint native proceedings and the decidedly civilised method employed by the chief operator.

#### Notes on Current Topics.

##### Alexander's Operation of Shortening the Round Ligaments.

THIS operation received its first practical demonstration as a surgical one in the metropolis, in March last, we believe, when Dr. Alexander, of Liverpool, the discoverer, whose name will for the future be associated with it, performed it in the theatre of the Soho Hospital

for Women. About that time Dr. Alexander was invited to deliver an address on the subject of his operation before the British Gynæcological Society, and last month, in fulfilment of the acceptance of the invitation, he delivered the address which will be found in another column. In addition to clear directions for the performance of the operation, it is curious to note that Dr. Alexander finds it necessary both to give a word of warning to the presumptuous, and one of encouragement to the discouraged. In truth, the operation is not so easy as some would have us believe, nor so difficult after a few trials as some beginners have found it. The history of the operation also is curious. As already noted by us, it was first suggested by Alguiè in 1840. Amongst the names already associated with it we may mention those of Freund, Hegar, Kaltenbach, Adams, Rivington, and lastly Professor Deneffe, of Gand. The latter stumbled on the idea whilst a student, and in 1864 wrote a doctoral thesis on the subject, and attempted the operation, but unsuccessfully, on the living body. Professor Deneffe has quite recently put forward his claims as the inventor of the operation in an article in *Les Annales de la Société de Médecine de Gand*, 1885, entitled "Raccourcissement des Ligaments Ronds pour la cure de la Rétroversion de la Rétroflexion et de la Chute de l'Uterus." If so many practical anatomists have independently hit upon the idea of the operation this alone is *prima facie* evidence of its feasibility, and looking at the subject now, it is almost matter of wonder that it was not worked out in a practical shape long ago. When so many good men have already worked at the subject and made nothing practical out of it, Dr. Alexander is to be congratulated on the signal success that has attended his efforts.

#### The Small-pox in Dublin.

At the last meeting of the Public Health Committee of the Dublin Corporation, Sir Charles Cameron reported the case of small-pox to which we alluded last week. The circumstances under which this case occurred were somewhat peculiar, and were stated to have been as follows:—In the report submitted some three weeks ago an outbreak of small-pox occurred in a house in Pembroke Road, the contagion having been carried in the person of a lady who visited the house from London. Four persons in the house were affected with the disease, and in two of these cases fatal results followed. Of the two fatal cases, it may be mentioned, one was that of a nurse from the Cork Street Fever Hospital, who, through the circumstances of her having been removed from Pembroke Road to the hospital, her treatment when suffering from the disease seems to have been subjected. At the conclusion of the outbreak at 71 Pembroke Road, which caused two deaths, the clothes of the patients were sent to a local laundry for the purpose of being washed, without any notification being given to the proprietor of the laundry to the conditions under which they were delivered. These clothes were washed along with other clothes, and, as a result, the affection appears to have been conveyed to one of the attendants in the laundry, who was admitted to Cork Street Fever Hospital with all the symptoms of small-pox. Sir Charles Cameron in his

report states:—"It was clear, then, that the disease had been imported into the laundry from the house in Pembroke Road." The Committee adopted the following resolutions on the subject, directing that that having reference to the compulsory notification of disease be transmitted to the Prime Minister:—"Resolved—That the recent case of small-pox occurring in a laundry in the neighbourhood of Dublin, by the inconsiderate, if not culpable action of a person sending infected articles to the laundry, is another proof of the urgent necessity for an act of Parliament enforcing the notification of infectious diseases." "That the Public Health Committee beg to draw the attention of the Pembroke Town Commissioners to the highly reprehensible conduct of a resident in Pembroke Road in sending to a public laundry the clothes of patients suffering from small-pox."

#### The Treatment of Inebriety.

THE recently published "Proceedings of the Society for the Study and Cure of Inebriety" for June last, contains an interesting paper by Dr. Muir Howie, in which the deprivation system is advocated on the ground that the will of the victim to drink is utterly incapable of being exercised in the least sense so long as the dominion of alcohol is in any degree maintained. In those cases in which *total* abstinence cannot be enforced it is advised that the indulgence should be postponed until as late an hour in the day as possible, on the ground that a man who drinks early also drinks deep. A case in point is quoted by Dr. Howie, being that of a man who under persuasion gave up the alcohol in which he had throughout his life indulged, and who found it less difficult to deny himself spirit when he took beer at supper time. Dr. Howie maintains that the condition named "nervous irritability" has a very real existence among drunkards, and that it should be accorded its place in the rules of treatment, and be met by exercise, fresh air, and bromide of potassium and quinine as remedies. A discussion followed the reading of the paper, in which the author's views generally were concurred in.

#### The Conjoint Examination Buildings.

DURING the past week an arrangement has been arrived at between the Royal College of Physicians of London and the Royal College of Surgeons of England, respecting a proposal to purchase a piece of land on the Victoria Embankment, on which to erect new buildings for the purposes of examination under the New Conjoint Board. It will be remembered that negotiations were opened some time since with a view to purchasing a site in Long Acre on behalf of the two Colleges: this scheme has, however, fallen through, and the Embankment site is the one which will probably be finally selected. The ground rent of the plot is £2,200 per annum, and it will afford very ample accommodation to meet all the requirements likely to arise. It is, we understand, the same site as was contemplated by those who endeavoured to get the General Medical Council to consent to the extravagance of a new Council chamber, and the non-success of which needless proposal was hailed at the time with such general satisfaction.

### Annual Dinner of Volunteer Surgeons.

ON Wednesday last the annual dinner of the Association of Volunteer Surgeons took place at the Freemasons' Tavern, the Right Hon. the Earl of Wemyss and March being in the chair. The gathering was a most successful one, no less than fifty gentlemen sitting down to dinner, among them being all the prominent surgeons associated with the Volunteer movement, and many of those attached to the Army Staff Medical Corps. The importance and duty of organisation was impressed on those present by the noble chairman, who expressed himself as enthusiastically devoted to the Volunteer Service now as when, as Lord Elcho, he was the principal promoter and champion of the movement. Previously to the dinner Surgeon-Major Evatt presided over a meeting of the Volunteer Medical Staff Association, when Mr. J. Cantlie, Hon. Secretary, described the recent work done by the Association, among the last improvements being the formation of a dining club for Volunteer surgeons, a scheme of the most promising character. A resolution was passed to fix the dinner annually to take place on the Wednesday immediately preceding the Wimbledon meeting, and it was further decided to extend the privilege of joining in the festival to members of the Volunteer Medical Staff Corps.

### Death from the Sting of a Bee.

It is announced that a man named Blanchard, an ironmonger, of Poole, died on Thursday last from the sting of a bee, which attacked him while walking in his garden a fortnight previously. The insect stung the deceased in the neck, and soon afterwards the parts swelled considerably and progressively, with the result given. It is rare in this country for such accidents to have a fatal termination, though it is not difficult to conceive such a constitutional state as should render any one so poisoned locally liable to risks affecting even life itself. In this case probably, inflammation extended along the lymphatic system into what Mr. Bryant very properly terms the dangerous region of the neck, where oedema and possibly suppuration into the cellular tissues around led to interference with the respiratory process; but the meagre accounts of the occurrence to be gleaned from the brief newspaper reports of the accident do not, of course, yield any information on this point. It would be very interesting to hear an account of the case from one or other of the medical men who were in attendance on the deceased.

### Ice Cream.

FOLLOWING the reported cases of several persons who were seized with illness soon after eating ice creams purchased from a particular vendor of these delicacies, a good deal of public uneasiness has been aroused with respect to indulgence in them. Dr. Muter has, therefore, devoted himself to a special investigation of the matter, and his report was on Thursday last communicated to the Lambeth Vestry, within whose jurisdiction the cases of alleged poisoning occurred. The samples analysed were three in number, and were purchased from a barrow in Lambeth Walk. Dr. Muter stated that, after a most exhaustive and careful examination, he had come to the

conclusion that nobody could suffer any injury from this article through anything unusual in its composition. It contained no poisonous matter, and the amounts of aniline colour and flavouring essence were so small as to be quite innocuous. Two of the samples actually contained fruit. Dr. Muter added:—"The mere fact of the hasty consumption of ice upon a hot day and an empty stomach would in itself frequently cause unpleasant results, even if no poisonous article were present."

### Death under Ether.

ON Tuesday, July 7th, a death occurred at the London Hospital during the administration of ether. The deceased was a woman, about forty years of age, who had been for some time under treatment, having been originally admitted with fracture of the right tibia, and also of the sternum. The latter injury became compound, and later on pyæmic changes took place, large collections being formed in the knee-joint and pelvis. Soon after being placed on the operating table, and when less than half an ounce of ether had been administered, respiration suddenly ceased, and though immediate and vigorous attempts to restore breathing by artificial means were resorted to, recovery did not take place, the patient never once rallying from the fatal syncope.

### The Work of the Middlesex Hospital.

WE have recently received the reports of the Medical, Surgical, and Pathological Registrars of the work done in connection with the Middlesex Hospital for the year 1883, and which make up a large octavo volume of considerably over five hundred pages. The amount of labour bestowed on this record of the year's work must have been very great, and the result is correspondingly valuable. The tabular arrangement and classification of the cases under treatment render the work exceptionally useful for reference, while for the same reason it gives it a permanent importance among case-books. The surgical portion of the work is a mine of information and suggestion, and is likely even more than the medical, to excite admiration, because of the greater readiness with which the histories of surgical cases lend themselves to be put in the form of brief abstracts: not that the medical and pathological reports are not equally praiseworthy; they deserve the highest praise throughout.

### The London Ophthalmological Society.

AT the annual meeting of this Society the following were elected as the Officers and Council for the year 1885-6, viz.—*President*: Jonathan Hutchinson, F.R.S. *Vice-Presidents*: Sir William Bowman, Bart., F.R.S.; George Johnson, M.D., F.R.S.; Thomas Reid, M.D. (Glasgow); T. Sympson (Lincoln); T. Shadford Walker (Liverpool); J. C. Wordsworth. *Treasurer*: J. F. Streatfeild. *Secretaries*: Seymour Sharkey, M.B.; W. A. Brailey, M.D. *Other Members of the Council*: John Abercrombie, M.D.; Sidney Coupland, M.D.; George Cowell; G. A. Critchett; Walter Edmunds; W. Adams Frost; E. Nettleship; Priestley Smith (Birmingham); Simeon Snell (Sheffield); J. B. Story (Dublin); John Tweedy; W. Spencer Watson.

**Mr. Erichsen's Parliamentary Candidature.**

It is announced that Mr. Erichsen, F.R.C.S., of London, has expressed his willingness to become a candidate, in the Liberal interest, at the general election for the representation of Edinburgh and St. Andrews Universities. His opponent on the Conservative side is the Lord Advocate, Mr. Macdonald, Q.C. Mr. Erichsen is to visit Edinburgh this week, and will probably address a meeting of his committee to-day or to-morrow. He has issued his address to the Members of Council, in which he promises that all questions relating to academic education, the proper relations of primary and secondary schools to the Universities, and those subjects depending upon the relations of science to public health and social welfare, shall receive his constant attention. Mr. Erichsen's character and professional position are such, and the necessity for medical representation in the House is so great, that we cannot but wish him every success.

**Precautions against Cholera.**

In the House of Commons last week Mr. Arthur Balfour, in answer to Lord C. Hamilton, who asked for information as to the steps being taken by Government to prevent the importation of cholera, told the House of Commons that the more extended inspection undertaken during the present year by six Government medical inspectors is now almost complete as regards the port and riparian districts of England, and is being pursued in other districts which there is reason to suppose would be most likely to suffer from cholera in the event of its introduction into this country. As a part of this inspection sanitary authorities are met and counsel taken with them, and their more immediate duty of preparation against cholera, as well as their general sanitary duties, are impressed on them by the Board's inspectors. The regulations which were in force during the prevalence of cholera in France and Italy are still in operation. As regards rags, an order has been issued prohibiting until the 1st November next the importation of rags from Spain.

**Foreign Bodies left in the Abdominal Cavity after Laparotomy.**

On February 20th, 1883, Dr. H. P. C. Wilson, of Baltimore, removed a dermoid ovarian tumour from a patient aged 29. After recovery from the operation a phlegmon formed in the cicatricial line above the umbilicus. This afterwards opened externally, giving exit to pus, and some months subsequently (July and August) ten pieces of sponge. The patient then recovered rapidly. As the sponges were carefully counted before and after the operation, and the number found to be correct, he could only account for the presence of the offending piece on the supposition that a fragment had become torn off during the process of cleansing—probably a not incorrect supposition. His own case led to an inquiry into the subject, and to the discovery of not less than thirty well-authenticated cases in which a foreign body has been left in the abdominal cavity after abdominal section. Of the thirty cases, thirteen occurred in America, and seventeen in Europe. The foreign bodies were sponges, pieces of sponge, or forceps—sponge

twenty-six times and forceps four. In five cases the presence of the foreign body was suspected, and search made for it in time to save the patient's life, and in Dr. Wilson's own case the sponge presumably became encapsuled and worked its way out as other foreign bodies sometimes do. The remaining twenty-four were all fatal, *i.e.*, presuming that the "ten other cases" given by Mr. Tait were fatal like his own. If the presumption is erroneous perhaps Mr. Tait will kindly correct it.

In addition to the above thirty cases given by Dr. Wilson, we are in a position to place a thirty-first on record, in which a sponge left in the abdominal cavity after laparotomy led to a fatal issue. As the surgeon to whom the misfortune occurred has not yet published the case, we should not be justified in giving any particulars that might lead to identification, but must limit ourselves to simply recording it as No. 31.

**New Appointments at the Glasgow Royal Infirmary.**

On the 2nd of August it will fall to the Directors of the Glasgow Royal Infirmary to appoint a physician and a surgeon; and we venture to express the hope that on this occasion, what was once the invariable rule of promotion from the subordinate position will not be departed from. In the first place, the Directors should take very good care that they appoint to the offices of Assistant-Physicians and Surgeons only such as should be promoted on vacancies occurring in the higher appointments; and secondly, it seems very unfair that when men have faithfully and efficiently discharged the inferior duties, as has hitherto been the case for many years without any pecuniary acknowledgment, and have undertaken the duties of full physicians to the house, as occasion demanded, that they should be superseded by men who have never been on the staff of the hospital, and in whose case exceptional circumstances to justify such a step are wholly wanting. For the office of Surgeon the contest, we understand, will lie between Dr. Newman and Dr. Fleming, and on the grounds we have mentioned we have no hesitation in saying that Dr. Fleming's claims are paramount. For the office of Physician two gentlemen not at present on the staff, *viz.*, Drs. McVail and Gemmell, are candidates, in addition the following members of the present staff:—Drs. Wallace Anderson, Dougall, Black, and Middleton. Drs. McVail and Gemmell are both able men, but we fail to see that this is a sufficient reason for installing them over the heads of the existing junior staff, some of whom have served the Infirmary in that capacity, and with the expectation of customary promotion for some years past.

**Frerichs' Successor.**

It is now definitely settled that Professor Leyden will succeed the late Professor Frerichs as Director of the first University Klinik, Berlin, and that Prof. Gerhardt, of Würzburg, will succeed to the post thus rendered vacant by Leyden's transference. The two kliniks will, however, for the future be placed on an equality in every respect, and will no longer be known as the first and second klinik, but by the names of their respective Directors.

### Atropine in Cases of Overdose of Chloroform.

M. GAYET, of Paris, has recently been making some experiments with a view of counteracting beforehand the depressing influence of chloroform on the heart. He has fixed upon atropine as the most suitable agent for this purpose on account of its stimulating effect on the cardiac beats. Twenty minutes before the operation he injects subcutaneously a suitable quantity of a solution composed of sulphate of atropine, 3 centigrammes, muriate of morphia, 20 c.g., distilled water, 20 grammes, and M. Gayet claims that since he has used this injection he has never had the slightest menace of danger in any of the numerous cases where chloroform has been employed as an anæsthetic.

### St. Andrew's Graduates' Association.

THE annual meeting of St. Andrew's Graduates' Association was held on June 30th. The following office-bearers were re-elected:—*President*: B. W. Richardson, M.D.; *Treasurer*: J. H. Paul, M.D.; *Secretary*: J. M. Menzies, M.A. The report of the Honorary Treasurer showed a balance of upwards of £90 in favour of the Association. A committee was elected to report to the Council on legislation as bearing upon the Scottish Universities, and upon the University of St. Andrews in particular.

### The Viceregal Medical Appointments in Dublin.

MR. ROBERT MOORE, F.R.C.S.I., has been appointed Surgeon-Dentist to the Lord Lieutenant, in succession to Mr. Corbet, who held office under Earl Spencer. We are not aware that any other appointments have been actually made, but it is assumed that Mr. Smyly and Dr. Hatchell will retain their offices as Surgeon and Physician respectively to the Viceroy.

### The Reuben Harvey Prize.

THIS prize was founded by subscription in 1882 in memory of Dr. Reuben J. Harvey, who died of typhus fever caught in the discharge of his duties as one of the physicians of Cork Street Fever Hospital, Dublin, on the 28th December, 1881, in the thirty-sixth year of his age. When he died, Dr. Harvey had acquired a high reputation as a physiologist, and the prize was established with the twofold object of perpetuating his memory and of encouraging original research in the department of physiology. It is to be awarded once in every three years to the writer of the best essay on a subject selected by the candidate, evidencing original research in animal physiology, including pathology, the essay to be illustrated by drawings or preparations, and the first award has just been made. Only one essay was sent in, by an author under the *nom de plume*, "*In cute curandâ plus æquo operata juvenus.*" The subject selected by him was "The Changes occurring in the Skin in some forms of Disease." The examiners for the prize—Dr. Walter G. Smith, acting on behalf of the President of the King and Queen's College of Physicians, and Mr. Phineas S. Abraham, acting on behalf of the President of the Royal College of Surgeons in Ireland—reported

most favourably of the essay, which was illustrated by 59 microscopical sections and several original sketches. The prize, the value of which is £20, was therefore awarded to Mr. Henry T. Bewley, Bachelor of Medicine and Bachelor of Surgery of the University of Dublin, who proved to be the writer of the essay.

### Hygienic Institution for Berlin.

THIS institution, forming part of the University of Berlin, was opened on the 2nd inst., under the direction of Professor Koch. It is expected that from October lectures will be delivered in it, not only by Prof. Koch, but also others, amongst whom Prof. Sell and Dr. Wolffhügel, the latter a pupil of Von Pettenkofer, are named.

### The Relations of Micro-Organisms to the Tissue Elements.

AT the last meeting of the Royal Society of Edinburgh a communication was made by Dr. Woodhead and Mr. Hare on the "Vital Relations of Micro-Organisms to the Tissue Elements." The authors discussed the various theories that have been propounded on the subject, and while adding little that is absolutely new, they marshalled in most systematic and thorough manner the already abundant, but widely scattered, material. Their paper, which, we observe, largely incorporates the opening chapter of their just published "Pathological Mycology," should form a fresh starting-point for workers in this important and enticing field. In reading the paper to the Society Dr. Woodhead reported that Edinburgh University was now thoroughly equipped for the prosecution of such research. Complete apparatus for bacteriological investigation had been fitted up in the Pathological, the Surgical, and the Practice of Physic Departments. They only required a band of earnest workers to ensure the obtaining of fresh results.

### The New British Pharmacopœia.

VERY diverse opinions have been current in literary and professional circles for some time past on the subject of the new Pharmacopœia. At the final meeting of the General Medical Council in May last it was mentioned that copies would shortly be in the hands of each member for final suggestion and revision; and it was imagined by some that each of the twenty-four members might be anxious to introduce his own particular crotchets, or endeavour to "improve" the work of the Pharmacopœia Committee to such an extent as to delay the publication indefinitely. Fortunately these predictions have not been verified. Having appointed a highly competent tribunal, with such a master-hand as Dr. Quain as chairman, the Council as a body were wisely content to leave the work as the Committee had presented it, and at the meeting of the Executive on Friday last it was decided to go to press with it at once, the first edition being fixed at 20,000, and the price six shillings per copy. We are in a position to state that the entire work has been thoroughly revised and brought up to date, all the new remedies of proved value have been incorporated, and that it will be larger by about one hundred pages than the previous edition.

### The General Medical Council.

WHEN the Council adjourned in May last, after its fortnight's Session, it was currently reported that an autumn meeting would be necessary to re-discuss certain medico-political and educational questions which were not then settled. We have authority for saying that the causes which led to this anticipation no longer exist, and that there will be in consequence no supplementary Session this year. This was decided at a meeting of the Executive last week, at which also a large number of charges were preferred by the Medical Alliance Association against qualified members of the profession for unprofessional conduct. These were eventually withdrawn after the opinion of the Council's law officers had been obtained, as not coming within the term of "infamous conduct," and the Executive separated after ordering the new edition of the British Pharmacopœia to be at once printed and bound.

WE understand that the President and Council of the Irish College of Surgeons have resolved to present to the Earl of Carnarvon an address of welcome on his assuming the Lord Lieutenancy of Ireland.

THE annual meeting and dinner of the Cambridge Medical Graduates' Club will be held at the Holborn Restaurant on this Wednesday evening, at 7.30 p.m., when Dr. W. H. Dickinson will be in the chair.

MR. FARRINGTON, M.R.C.S., proprietor of the Shelvinger Spa, Norfolk, recently opened his grounds for a public fête, the proceeds from which were generously handed over to the Norwich Hospital, and to some other local charities.

A SERIOUS fire occurred on Saturday morning at the Northumberland House Private Lunatic Asylum, Stoke Newington, by which two blocks of buildings containing twenty rooms were completely destroyed, and a third nearly so. No injury resulted to any of the patients.

## Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

DEATH OF DR. AULD, OF GREENOCK.—We regret to have to announce the death of Dr. Auld, the oldest medical practitioner in Greenock, which took place on the 6th inst. The deceased was 85 years of age, and was a native of Greenock, his father being the first minister of the Relief Congregation there. Deceased was licensed as a medical practitioner in 1820. He held the appointment of Prison and Police-Surgeon for over thirty years, and since the Factory Act passed he had been Government Inspector under the Act. He was held in high respect by all classes of the community.

PROPOSED SOUTHERN HOSPITAL FOR GLASGOW.—It is now more than four years since a committee was appointed "to arrange for a site, obtain subscriptions, and prepare a constitution and rules for the management of a hospital, to be hereafter submitted for approval to a meeting of those who may agree to subscribe to the funds thereof." As a result of the representations made by this committee to the

Glasgow Corporation a very eligible site was obtained, consisting of four acres of ground on the south side of the river. Designs were obtained and selected, and it was shortly afterwards announced that owing to the death of Mr. Robert Couper, of Cathcart, a large sum would fall into the hands of the committee from a will which he had executed, leaving the residue of his estate to be devoted to the erection of an hospital and convalescent home on the South Side. The committee, in ignorance of the amount of this bequest, delayed for a considerable time any active exertions to obtain subscriptions from the public. They have now, however, been informed by Mr. Couper's trustees that the residue of the estate is smaller than was anticipated, and that a great part of it may not even be available for the purposes mentioned for many years. Accordingly the committee, considering the urgent necessity for the immediate erection of a Southern Hospital for those who are unable to obtain admission to the existing hospitals on the north side of the river, and considering that already about £7,000 has been subscribed for the erection of the Southern Hospital (including a legacy of £2,000 by the late Mrs. Dixon, of Govanhill) have resolved to commence building operations at once, and to construct, in the meantime, only a portion of the proposed infirmary, waiting for further contributions before completing the design.

EDINBURGH ROYAL MATERNITY AND SIMPSON MEMORIAL HOSPITAL.—The new quarter commences on the 1st August, when Dr. Halliday Croom succeeds Dr. Keiller as physician on duty. Dr. Berry Hart succeeds Dr. Underhill as assistant physician, while the present house-physicians, Dr. William G. Anglin and Mr. Wm. Cotton, M.B., C.M., will be succeeded by Mr. J. Haig Ferguson, M.B., C.M., and Mr. S. H. Puckle, B.A.

THE PROPOSAL TO OPEN THE CENTRAL MEADOW WALK, EDINBURGH, FOR CARRIAGE TRAFFIC.—A large public meeting was held in the East Meadows, Edinburgh, on Friday evening, to protest against this unwise proposal, to which we referred some weeks ago. It will be remembered that the walk separates, or rather unites, the new medical buildings and the Royal Infirmary. The authorities of both these institutions have protested against the movement. The meeting, it was hoped, would be presided over by Professor Rutherford, F.R.S., but he was unfortunately unable to be present. Vigorous addresses were made by a number of Edinburgh citizens. *Tantus labor non sit cassus!*

EDINBURGH UNIVERSITY.—NEW EXAMINATION HALL.—Graduates of Edinburgh University will read with interest that the late Anatomical Museum in the north-west corner of the old University buildings, from which the specimens have been transferred to their spacious home in the new buildings, is rapidly being transformed into an Examination Hall. The clear space obtained by the inclusion of some adjoining rooms will supply accommodation for 240 students during a written examination. The alterations will cost about £1,000. They are being pushed on rapidly, and it is hoped that the hall will be ready for use at the commencement of the approaching winter season.

The Mortality of Foreign Cities.—The annual death-rates per 1,000 in the principal foreign cities, according to the last weekly returns communicated to the Registrar-General, are as follow:—Calcutta 25, Bombay 24, Madras 35, Paris 20, Geneva 21, Brussels 20, Amsterdam 20, Rotterdam 18, The Hague 24, Copenhagen 21, Stockholm 27, Christiania 14, St. Petersburg 25, Berlin 24, Hamburg 24, Dresden 25, Breslau 38, Munich 32, Vienna 34, Prague 42, Buda-Pesth 29, Trieste 30, Rome 22, Turin 25, Venice 23, Alexandria 29, New York 25, Brooklyn 19, Philadelphia 19, and Baltimore 13.

HOSPITAL INQUIRY COMMISSION.
issued to each of the Dublin hos-
pitals from Government a series of 34
questions deal with the composi-
tion of the hospital and the discharge
of its members of that body; the method
of the accounts; the efficiency of
the education, and the number of stu-
dents; the nursing system; and, lastly, the
appointment, and discharge of their
officers.

Correspondence.

IN HIS OWN M.D.

THE MEDICAL PRESS AND CIRCULAR.
I permit me to quote, with much ap-
preciation from the letter of a double-
degree holder which appears in the columns of one

of a diploma or a degree is in
proportion of obtaining it, which
is never that done by others; and
is recognised not only by the pro-
fession, but by the public. Now there
is a great call out for some of the
profession; and a university, which
is to grant the diploma to any doubly
qualified man who is a certain subject.
What is it that we want? Is it merely
to be able to do some of the things
which are done by others? or is it so
that they may be better than they are?
or what?

to write M.D. after their names.
is it an honour? We know some
of the M.D. who prescribe for sixpence,
and who oppose tradesmen. So the fact
is not to our advantage. Let those
that are of M.D. from anywhere they
are, so far as I can see; if a man
sides, would be as good as any

Is it not a fact that, having
degrees and diplomas, and seeing the
advantage of holding good degrees as M.D.,
on the same footing as they are—
done more work, if not actually
of the sciences? Is it fair to them

said, the value of a degree
of the faculty of obtaining it. And
of a new university which is
in its arms to doubly qualified
of the degree as a degree?

little further than the writer of
of the profession to the practitioner who
of earning the title. Why need
of a sham, to get the degree?
of his mind that he is, by educa-
and has he not been assured by
of his that he has by virtue of his
of his double diploma, quite as good
of an M.D.? Why then need he
of a degree shop for a privilege which
of confer on himself as they are to
of the M.D. conferred by Mr. Jones,
of much a Doctorate as if it were
of a limited liability company, consti-
of tuted of those who are, individually, M.R.C.S.

by the process of annexation.

DUB. UNIV. AND F.R.C.S.I.

THE INFLUENCE OF SEA-VOYAGING UPON THE GENITO-UTERINE FUNCTIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Referring to the influence of sea-voyaging upon the genito-uterine functions, of which Dr. J. A. Irwin has ably demonstrated the truth in your columns, I may mention a case that has fallen under my own observation, and which seems to be strikingly confirmatory of this fact. A young lady in India, of leuco-phlegmatic temperament, and remarkable for want of energy, which was conspicuous even in her languid mode of speech, had been married for seven years without any prospect of having a family, there not having been the slightest indication of pregnancy during the whole of this period. The husband was also young, and in good health. Being, however, of a kindly disposition, and never expecting to be as ladies wish to be &c., &c., Mrs. A. surrounded herself with pets—small dogs, birds, and a monkey. At the end of the seven years she accompanied her husband (a civilian) to England on furlough. They went by the long sea route round the Cape (of Good Hope). In those days—I speak of thirty years ago—a voyage home in a sailing-vessel (one of the large passenger ships of the time) was very invigorating. A comfortable cabin—one's own private residence for three months at least, so different to the comfortless system of berths in a general cabin in a so-called overland steamer—the soothing influences of the sea, the tonic air, &c., &c., all combined, provided one was abstemious in the matter of food and intoxicating drinks somewhat freely provided in most of these vessels, to produce (in good sailors) a vigorous state of health which, coming after a lengthened sojourn in a hot climate, was especially enjoyable. The lady became pregnant on board; and the activity of the reproductive function (thus roused) being maintained for several years, even after the return to India, this pregnancy was followed by others: and, as a matter of fact, a child was born annually for ten successive years, the deficiency of the first septennial period being rather too prolifically made up afterwards.

I have been six times round the Cape in passenger vessels and four times overland, and I quite believe in the stimulating effect—not always for good—of a sea-voyage (long or short) upon the ovario-uterine organisation. In prescribing this remedy, however, in cases of sterility, the medical practitioner might, with the experience of that just related, be inclined to pause, feeling that possibly his patient might hereafter tax him with having prescribed rather too much of a good thing!

I am, Sir, yours, &c.,

CHAS. R. FRANCIS (Surgeon-General).

Clapham Common, S.W., July 1, 1885.

MR. LAWSON TAIT AND VIVISECTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I enclose a report of Mr. Coleridge's speech, in which the statements in the report of Mr. Busk are challenged. It is not for me to say whether it is the reporter or the experimenters who make the statements therein refuted, and of course it is quite possible that there may be some explanation by which both may be excused from the charge of misrepresentation. But as the matter stands at present, and without complete explanation, I say again that the honour of our profession is made grievously to suffer by the statements advanced by Mr. Coleridge.

I am, &c.,

LAWSON TAIT.

Birmingham, July 9th, 1885.

[If Mr. Lawson Tait will insist on taking his "facts" from the organ of the anti-vivisection party, it seems to us useless to argue the question further. It is very evident that the "figures" relied upon by him are made to square with "facts" which are absolutely unreliable; while of the veracity of the gentleman who sought to impose them on a sympathising audience we have had, of late, more than enough. It is, at all events, a fact that he is the representative, on this particular question, of a class who, hating light, desire to set bounds to the acquisition of knowledge by

others, retaining only just so much as may suit their limited intelligence. Such people are, as might be expected, quite incapable of understanding the aim and object of those who pursue physiological inquiries less for their own good than for the good of others, for the amelioration of human suffering, and the prolongation of human life.—ED.]

### LABORATORY NOTES

#### ON SOME NEW PHARMACEUTICAL PREPARATIONS AND INVALID REQUISITES.

By F. J. B. QUINLAN, M.D.,

Professor of Materia Medica, Pharmacology, and Therapeutics, Catholic University Medical College; and Examiner in the same, Royal University.

##### LIQ. EUONYMIN ET. PEPSIN CO. (OPPENHEIMER'S).

EVERY practical physician is familiar with the efficacy of euonymin as a hepatic stimulant, and pepsin has passed into the list of therapeutical requisites. Messrs. Oppenheimer Bros. and Co., of London, furnish an excellent liquor euonymin and pepsin which appears to combine very well the properties of both remedies. I have tried it (in doses of a teaspoonful at every meal) in several cases of atonic dyspepsia with torpidity of the liver, and with the best results. Tried by the egg albumen process [see Laboratory Report upon 'Digestive Ferments,' *Medical Press and Circular*], a dram of the liquor at 130° F. effectually peptonises gr. 72.3 of egg albumen previously triturated through the standard gauze. This is a result of the most satisfactory kind, and one which none but the very best pig pepsins will equal.

##### MEAT ESSENCES.

The essence of beef produced by the London Manufacturing Company is, we are informed, the first successful effort in the manufacture of an absolutely pure and transparent beef essence, without the addition of gelatine, and it promises to become a valuable adjuvant in the sick room from its strengthening and invigorating qualities, as well as its bland and unirritating character. Careful filtration through paper shows that the fat has been completely removed, and that the essence consists of a pure and highly nitrogenous jelly of the colour and consistence of ordinary calves' foot jelly, with a distinct, but agreeable, beef taste. It is best taken cold, but can be easily warmed, in which case it resembles beef essence made in the ordinary way, but more highly refined. In cases of prostration it may be taken in teaspoonfuls as often as it can be swallowed, when it will have a pronounced stimulating effect; in ordinary cases the dose is a tablespoonful three times a day. I have tried it in cases of the convalescence of enteric fever with the best results, and in teaspoonful doses in a case of persistent vomiting owing to alcoholic gastric irritation. In this case it had a decidedly sedative effect upon the stomach, and relieved that sense of præcordial sinking and distress which is characteristic of chronic alcoholism. The compound is evidently extracted from good beef, very carefully made in steam jacket apparatus, and without the aid of water. The same company manufacture a concentrated beef tea, which is apparently ordinary well made beef tea evaporated down to a jelly, but not so highly refined as the transparent beef essence. To prepare it for use it is merely necessary to add some of it to a proper quantity of boiling water, and to complete the process with it, salt or season to taste. An agreeable dark yellow beef tea is produced, which cannot be distinguished from the best fresh cooked article. This concentrated beef tea also forms a capital stock for many invalid soups. The benefit of the preparations to travellers, military surgeons, and persons living in chambers, cannot be over estimated. In fact in every family, no matter how effective the *batterie de cuisine* may be, they will be useful in emergencies.

##### A NEW DISINFECTANT—ZYMOLYS.

A new disinfectant, Zymolys, is brought forward through the agency of Messrs. Barclay & Sons, of London. It is intended for internal administration, and is stated by the manufacturer to fortify the system against the ordinary

zymotic diseases. Whether it can accomplish this great benefit experiment alone can determine. In the meantime, however, it must be said that it is agreeable to the taste and perfectly harmless.

## Literature.

### BRYANTS SURGERY. (a)

THE fourth edition of Mr. Bryant's useful text-book of surgery shows evidence of the influence exerted by modern improvements, not alone in the superior excellence of many of the operations described in the work, but as well in the character of the book itself, which has benefited in many places by the revision it has undergone, and for which it is likely that the spirit of healthy competition is largely to be credited. There was never, indeed, a time more favourable than the present to the student, so far as his choice of manuals of instruction in the science and art of surgery is concerned, for we have recently witnessed such a succession of new treatises, and new editions of old ones in connection with this branch of medicine—and many of them of permanent sterling value—as is almost productive of embarrassment. Among them all, however, none can claim superiority in point of practical utility over the now firmly established manual with which Mr. Bryant is identified, and to the success of which his well-earned reputation as a surgeon is partly attributable.

The alterations from the third edition are numerous and important. The progress of scientific research has necessitated a good deal, not merely of revision, but of actual re-writing also, the chapters dealing with inflammation and with tumours especially, having been carefully brought into agreement with the most recent advances. The unprecedented progress made in the field of renal surgery of late has likewise necessitated material alterations in the section dealing with operations on the kidney; and a full and complete account of Bigelow's operation of lithotripsy at a single sitting enhances the value of the chapter on lithotripsy and lithotomy. The several methods of removing the tongue brought into prominence in recent discussions are fully treated, as well as the new operation of colectomy. Charcot's joint disease receives consideration, and as well all the other modern subjects of discussion, to which prominence has attached, since the former edition of the work was published. In the matter of illustration the manual is very greatly improved, a liberal use of wood-cut engravings having been wisely resolved on; in addition further to these, of which eighty-four new ones are introduced, a number of admirably executed chromo-lithographic plates depicting diseases of the tongue, breast, &c., are incorporated in the work, and add greatly to the value it possesses as a text-book.

We shall be acquitted of hypercriticism if we suggest a more careful revision of the letter-press in view of a future edition. Occasional confusion of tenses, persons, and case detract from the literary finish of a manual which for practical excellence as a guide to the science and art of surgery is one of the most admirable of English high-class treatises.

### HAY FEVER. (b)

A YEAR has just elapsed since we had occasion to notice a former edition of this most interesting and important *brochure*. The conciseness and lucidity of statement which pre-eminently characterise it have met with a just reception, and a third edition has been called for. The general plan of the work remains the same, but its bulk has been increased by the addition of a good deal of new matter, chiefly critical, with regard to the opposing views enunciated by American physicians. Dr. Morell Mackenzie cleaves firmly to the etiological importance of the pollen, and gravely questions whether abnormal conditions of the nasal cavities are of much value as a factor in producing hay fever. He maintains further that it is a mistake to predicate greater sensi-

(a) "A Manual for the Practice of Surgery." By Thomas Bryant, F.R.C.S. Fourth Edition, in two Volumes. London: J. & A. Churchill.  
(b) "Hay Fever: its Etiology and Treatment. With an Appendix on Rose Cold." By Morell Mackenzie, M.D., London, Lecturer on Diseases of the Throat at the London Hospital Medical School, &c. Third Edition. London: J. & A. Churchill, 1885.

tiveness of special portions of the nasal mucous membrane. As the result of a large number of experiments he finds that the most sensitive spot varies in different individuals and in the same individual at different times. Moreover, rhinoscopic examination of a number of typical cases of hay fever demonstrated the absence of a morbid condition of the interior of the nose. Probably a number of the American cases will, in the end, be proved to be exceptional. Certainly the vast majority of patients suffering from chronic disease of the nose do not suffer from hay fever. We agree with Dr. Mackenzie in thinking that the nose is perhaps receiving too marked attention just now. It would appear as if there were a risk of its robbing the dreaded bacillus of some of its triumphs. The essay has also been enriched by an interesting appendix on Rose Cold—an affection long known in America, but of far less frequent occurrence on this side. We should again recommend all who are interested in the subject to make themselves acquainted with this store of exact and varied information.

#### PLANT ANALYSIS. (a)

PROFESSOR DRAGENDORFF is one of the numerous Germans whom Russia has recruited into her service; and it appears to us that he has in the present volume solved a difficulty hitherto formidable to the pharmaceutical chemist. His plan consists of exposing the plant to a series of solvents, commencing with a very volatile petroleum spirit, which takes up the chlorophyll along with the volatile fatty oils and wax, but leaves untouched the resins, and avoids the primary difficulty of coagulating the soluble albumen. The plant is next exposed to ether, which takes up the resins; and then to absolute alcohol for tannin and the alkaloids. Water now removes the mucilage acids and sugars; and the process is completed by diluted soda and subsequently diluted hydrochloric acid. The work is intensely practical; and long pages show the patient work at the laboratory table explained in the clearest and simplest style. The translation has been accomplished by Mr. H. G. Greenish in the most admirable manner and with complete fidelity to the original. We consider that this volume will supply a want which has long been felt by every pharmaceutical inquirer.

#### PEARCE GOULD'S SURGICAL DIAGNOSIS. (b)

A REALLY useful manual of surgical diagnosis was one of the most needed books required by medical students, and in supplying this long-felt want Mr. Pearce Gould has conferred a signal benefit on numbers who will be ready to appreciate his services. It is not, however, to be said that in writing the "Elements" its author has done the work as perfectly as might be desired, for excellent as it is on the whole, the book is still not without shortcomings, the absence of which would leave it a more admirable student's guide than it is at present. Principally we would urge against it that it is too voluminous; not that it can be said with any truth that the subject matter is dealt with at too great length, but that an error of judgment has been committed in deciding against any tabular arrangement of the contents of the book. While appreciating the justice of Mr. Gould's excuses for discarding this mode of presenting differential points, we still incline, from observation among them, to think that average students most frequently succeed in grasping important details in this connection when presented in such a form to their intelligence. It is futile to look for philosophical thought in ordinary students of medicine, and we humbly submit that manuals designed for their instruction should recognise their shortcomings and teach them in a way best fitted to make them careful and trustworthy practitioners.

With this, we trust not ungracious, piece of criticism, fault-finding with the book must end; for a most careful perusal of its whole contents enables us to speak in the highest terms of its utility as a guide to the diagnosis of injuries and surgical diseases. A good example of the excellence of its directions is afforded in the chapters dealing with fractures and dislocations, the nature and diagnosis of which, especially those of the hip, shoulder, and ankle, are often cause of con-

fusion to students. Mr. Pearce Gould has succeeded in putting the subject in a clear and comprehensive fashion that will be a source of much satisfaction to many a puzzled reader of other descriptions; and similar terms might be employed of several other difficultly recognisable injuries.

#### GOODHART'S DISEASES OF CHILDREN. (a)

DR. GOODHART'S "Diseases of Children" is a new volume in Churchill's well-known series of manuals for students of medicine, and was, its author tells us, undertaken in deference to the wishes of many medical students desirous of possessing a small handbook on the subject. It almost naturally goes without saying that the volume is an exceptionally good introduction to the subject on which it treats, for the reputation enjoyed by Dr. Goodhart, both as an observer and as a teacher, renders it difficult to imagine him doing less than ample justice to any task he was satisfied that he could undertake, and an examination of the book itself fully confirms such anticipation of its value. It is in all essentials a "student's manual," and is from cover to cover admirably calculated to advance its readers in practical knowledge of, and ability to treat, a class of cases which more usually than not cause junior practitioners a degree of embarrassment most unpleasant to experience.

The chapters dealing with disorders of the nervous system are most carefully written, and the discussion of chorea and its pathological causes will well repay a more than ordinary reading. The articles on rickets, syphilis, and skin diseases are also full of especially suggestive matter, and it may generally be said of the book that no part of it will fail to attract the deepest interest of all who will give their attention to it. On treatment much useful information is given, and not a little assistance will be obtained from the records of cases under his own care, which Dr. Goodhart gives whenever such a course helps to elucidate his meaning. A number of formulæ are contained in an appendix, and will be found very serviceable. The book is in every way a most desirable addition to "Guides" issued by Messrs. Churchill.

### Medical News.

University of Edinburgh.—FINAL EXAMINATION IN MEDICINE.—The following is an additional list to that which appeared in our last, of candidates who have passed the final examination, viz.:—Robert Jackson, Hugh Jamieson, Hugh John, Thomas Johnstone, M.A.; Samuel Baker Jones, Robert Conway Joyce, David James Lawson, Charles Ashley Scott Leggatt, Robert Fraser Calder Leith, M.A. (with distinction), Charles James Lewis (with distinction), Reginald Horace Lucy (with distinction), James Smith McCracken, Duncan M'Diarmid, Henry Cox M'Ewen, B.Sc.; William Mackay, M.A.; Frank Wallace Mackenzie, Frederick Lumsden Mackenzie, Hector Rate Maclean, William Henry M'Lean, Robert Maclelland, John Macdonald MacLennan, M.A.; Alexander Ronald Macmillan, Robert Charles Macwatt, Daniel Grove Marshall, James Williamson Martin, David James Mason, Charles G. Matthew, Henry Bruce Melville, William Francis Menzies, William Cornfoot Miller, William Gordon Mitchell, M.A.; Robert Selkirk Morrison, William Murphy, William Ramsay Nasmyth, Frederick Augustus Neal, Johannes H. Neithling, Walter Blake Nisbet, Ernest Stanley Nutting, Glenmore Ozanne, John William Pare, Sydney Partridge, Ian Paterson, Maurice Paterson, Thomas Jackson Thyne.

National Dental Hospital and College.—The annual distribution of prizes to the successful students of this institution took place at the Beethoven Rooms, Harley Street, on Monday, the 6th instant, with Dr. Alfred Carpenter in the chair. Messrs. Poole, Douthwaite, Lombardi (2), and Perks were presented with medals, while Messrs. Lovitt, Tucker, Carter, Rymer, and Fisk received certificates of honour. Mr. F. Wright was awarded the prize for the best paper read before the Students' Society for the year 1884. After the distribution Dr. Carpenter delivered a short address, and the rest of the evening was passed in a very pleasant manner, thanks to the ladies and gentlemen under the direction of Mr. Selwyn Graham, who executed in a most satisfactory style a very *recherché* programme.

(b) "Elements of Surgical Diagnosis." By A. Pearce-Gould, M.S., M.B. (Cassell's Students' Manuals.)

(a) "The Student's Guide to Diseases of Children." By James Frederick Goodhart, M.D., F.R.C.P. London: J. & A. Churchill.

## Notices to Correspondents.

**LOCAL REPORTS AND NEWS.**—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

**MR. DAWSON.**—We cannot say at the moment how far the influence of the remedy may be felt. We should think your own estimate is very probably a correct one.

### THE PHYSICIAN'S DIPLOMA OF EDINBURGH.—A QUERY!

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—A. B., a surgeon and physician of Dublin, finds that he cannot keep open a private surgery with the physician's diploma. He is desirous of obtaining the physician's diploma of Edinburgh, and wishes to know if he is admitted a licentiate by paying the examination fee and making the usual declaration, or is he subjected to the ordinary examination, or exempt from any subjects, and what?

By answering the above question in your next issue you will very much oblige

Yours, &c.,  
PHYSICIAN.

[The candidate will have to pass a written and oral examination in medicine, clinical medicine, materia medica, midwifery, and medical jurisprudence. The fee is £15 15s.—ED.]

**DR. THORNTON.**—The "Dictionary of Medicine," edited by Dr. Quain, is most likely to be useful to you in such circumstances as you name. Phtisis is one of the subjects which are most fully treated, and with reference to the most recent discoveries and theories.

A. A. P.—Your case is one for treatment by a surgeon.

### DISFRANCHISEMENT FOR MEDICAL RELIEF.

THE Government introduced a clause yesterday (Tuesday) in the House of Commons with the object of removing the disabilities in the new Franchise Bill. The opposition is not expected to be serious.

**DR. WHITE.**—The circumstances of the case are already known to us, and we consider the circumstances are such that no excuse is possible. The matter will be fully referred to in our columns.

### THE PATENT MEDICINE ACT IN THE HOUSE OF COMMONS.

At the present advanced stage of Parliamentary business, the Government could hardly be expected to bring forward so contentious a measure as the removal of the Patent Medicine Stamp Act, but they have given us a "sop in the pan" in the shape of a promise that the stamp shall not in future be used for the purposes of fraud, but that henceforth words shall be printed on the said stamp that it affords no Government guarantee against poisonous ingredients.

**A LONDON HOSPITAL STUDENT.**—We have referred to the articles entitled "In a London Hospital by an In-patient" in a contemporary, and find they are the same as declined previously by us because of their many inaccuracies. Those pointed out by you are but a few of many, and alone would have justified our refusal. We do not think any good purpose could be served by their exposure, as no particular hospital is referred to.

### A PHYSICIAN WANTED IN CORNWALL.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—The city of Truro is in the centre of the population of the county of Cornwall, which population numbers about 80,000 persons. The city of Truro itself contains 11,000 persons, and within a few miles there is a population not far short of 80,000 souls. For many years Truro always had three physicians resident therein, but of late two only. Of these two, one has recently died, and the last surviving physician is now 70 years of age. He has just retired, in consequence of advancing age, from the post he has long held as honorary physician to the Royal Cornwall Infirmary, which institution is therefore at the present time without a physician, although there are probably fifty or sixty in-patients in the house, besides a larger number of out-patients.

The office of physician and surgeon of the Royal Cornwall Infirmary has always been an honourable and hitherto much-coveted office, and it does therefore appear inexplicable that no one has applied for the office known to be vacant. Speaking for myself and many others, I can confidently state that a physician of good acquirements, with good tact and comely presence, combined with a sincere desire to do good in his generation, would command and receive a kindly greeting in the good city of Truro.

I may add that within my own knowledge fees of £10, £15, £25, and even £50 have been paid of late to have the opinion of men of good position supposed to be well versed in the healing art.

A FATHER OF A FAMILY.

Truro, July 4th, 1885.

**R. P. I.**—You have not mentioned any authority. Of course, no notice can be taken of the occurrence until we are fully assured of the truth of the statements laid before us. If no further explanation is offered, it will be difficult to perceive any reason for the course that has been followed. We shall be glad to have full particulars.

### WATERPROOF GARMENTS FOR DOCTORS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—I am obliged to work my practice almost entirely on horseback, and, now that years are increasing, I find the discomfort of remaining often for hours in wet clothes. I have tried various kinds of india-rubber waterproof overcoats, and discarded them long since, owing to their preventing exhalation, and thereby rendering the inner garments uncomfortable. I have also tried saturating the cloth with solution of "acetate of lead and aluminum sulphate," recommended for waterproofing, and found it useless. If any brother practitioner similarly situated knows the maker of a warm rainproof durable

riding-coat—also light, as I am rather a heavy weight—I shall feel greatly obliged to hear of such in your "Answers to Correspondents" column.

I am, Sir, yours, &c.,

MYOSOTIS.

July 6, 1885.

**DRS. VERNON RUSSEL AND DANIEL MOLONY.**—We regret the necessity of publication of the case on "surgical and ethical" grounds. We will, however, afford space for same in our next issue.

## Vacancies.

- Buenos Ayres.**—Resident House Surgeon to the British Hospital. Salary, £200, rising to £250, with board, &c. Applications to House Surgeon, E. A., care of Burgoyne & Co., 16 Coleman Street, London.
- Chelsea Hospital for Women.**—Resident Medical Officer. Salary, £60, with board. Immediate applications to the Secretary.
- French Hospital, London.**—Resident Medical Officer. Must speak French. Salary, £60. Applications to the Secretary at once.
- Manchester Royal Infirmary (Monash Fever Hospital)**—Assistant Medical Officer. Salary, £50 per annum, with board and residence. Applications, with testimonials, to the Chairman of the Medical Board, immediately.
- Manchester Royal Infirmary, Dispensary, and Lunatic Hospital or Asylum.**—Honorary Obstetric Physician. Applications, with testimonials, to the Chairman of the Board, not later than July 18.
- Royal Cornwall Infirmary.**—House Surgeon. Salary, £150, with furnished apartments, &c. Applications, with testimonials, to the Secretary, before July 18.
- St. Thomas's Hospital Medical School.**—Demonstrator of Physiology and Practical Physiology. Applications to Mr. G. Rendle, at the Hospital.
- Western General Dispensary, London.**—Assistant House Surgeon. Salary, £68, with apartments. Applications to the Secretary, Marylebone Road.
- York County Hospital.**—Resident House Surgeon. Salary, £100 a year, with board and lodging. Applications, with testimonials, to the Secretary, on or before July 25.

## Appointments.

- DREWITT, F. G. D., M.D. Oxon., M.R.C.P. Lond.,** Physician to the West London Hospital, Hammersmith.
- HERBERT, C. M., M.D., C.M. Ed.,** an Honorary Physician to the Bradford Infirmary.
- HEWITT, F. W., B.A., M.B. Cantab.,** Anaesthetist to the Royal Hospital for Children and Women, Waterloo Bridge Road, S.E.
- HUGHES, S., M.B., C.M. Ed., M.R.C.S., L.S.A. Lond.,** House Surgeon to the Liverpool Royal Infirmary.
- LONGMAN, G. P., L.R.C.P. Ed., M.R.C.S.,** Medical Officer for the Donhead District of the Tisbury Union.
- MEDCALF, E. S., L.R.C.P. Ed., M.R.C.S., L.S.A. Lond.,** Medical Officer for the First District of the Steyning Union.
- MOODY-WARD, R., B.A., M.B. Oxon., M.R.C.S.,** House Physician to Guy's Hospital.
- PHILLIPS, F. B. W., M.A., M.B. Oxon., M.R.C.S.,** House Physician to Guy's Hospital.
- QUEENELL, R. W., M.R.C.S., L.R.C.P. Ed.,** Junior Resident Officer to the Royal Free Hospital.
- RODMAN, J. H., M.B., M.R.C.S.,** House Surgeon to Guy's Hospital.
- SQUARE, W. H., L.R.C.P. Ed., L.R.C.S. Ed.,** Medical Officer of Health for the Stow Rural Sanitary District.
- TAMMER, C. E., M.B. Durh.,** Junior Resident Medical Officer to the Royal Free Hospital.
- WEIGHTMAN, A. E., L.R.C.P. & L.R.C.S. Ed.,** House Physician to the Liverpool Royal Infirmary.
- WORTHINGTON, S., M.B., F.R.C.S.,** House Surgeon to Guy's Hospital.

## Births.

- BARNES.**—July 10, at 15 Harley Street, London, W., the wife of Robert Barnes, M.D., of a daughter.
- CLARK.**—July 11, at 19 Cavendish Place, London, W., the wife of Andrew Clark, F.R.C.S., of a son.
- HODGES.**—July 8, at Guildhall Street, Bury St. Edmunds, the wife of James Hodges, M.R.C.S. Eng., prematurely, of a son.

## Marriages.

- COOKSON-ANSTAY.**—At the Parish Church of Slapton, Buckinghamshire, Henry Cookson, F.R.C.S., of Woodstock, Eastbourne, to Alice Mary, only surviving daughter of the Rev. H. Anstey, Rector of Slapton.

## Deaths.

- BARKWAY.**—July 5, at Grove House, Lavenham, Suffolk, Frederick T. Barkway, M.R.C.S. & L.S.A. Lond., aged 69.
- KEMP.**—June 28, at Ivy Cottage, Pliton, Barnstaple, George Kemp, M.D. Cantab., aged 77.
- SALMON.**—June 29, at his residence, Castlepollard, Thomas Salmon, M.D.
- WILLIAMS.**—July 7, at Riversdale, Templeogue, James E. Williams, M.D., Inspector-General of Hospitals, aged 81.
- WOOD.**—July 7, at his residence, Philbeach Gardens, Earl's Court, Arthur Wood, M.D., late of Her Majesty's 9th and 10th Lancers, aged 79.

## Clinical Lecture

ON

### DYSMENORRHŒA.

Delivered at the Chelsea Hospital for Women.

By FANCOURT BARNES, M.D., M.R.C.P.,

Obstetric Physician to the Great Northern Central Hospital; Physician to the British Lying-in Hospital, and the Chelsea Hospital for Women.

GENTLEMEN,—When the menstrual function is performed with difficulty and pain, the condition is described as dysmenorrhœa. The chief conditions of the uterus and its appendages which may give rise to it are as follows:—1. Neuralgia; 2. Congestion or inflammation; 3. Mechanical or obstruction; 4. The formation and expulsion of membranous casts; and 5. Some forms of ovarian disorder.

Every woman suffers to some extent during menstruation. It is only when pain is excessive that it is regarded as dysmenorrhœal. The term neuralgic dysmenorrhœa has been retained, and is still used to describe those cases in which no tangible disorder of the uterus or its appendages can be verified. If, however, the uterus and ovaries were healthy there would be no difficulty in the discharge of their functions. The symptoms, however, are obvious enough, though it may be impossible to recognise a definite cause. The menstrual epoch may be ushered in by such intense pain that the patient is compelled to take to her bed. The abdomen is often tender to the touch. The reflex symptoms which may evoke, are of a neurotic nature. Vomiting, hysteria, hiccough, headache, delirium, and even mania may occur. These urgent symptoms decline in a few days, and the patient is relieved until the reappearance of the same train of symptoms at the next menstrual epoch.

Now, although in the first instance no obvious organic change can be detected in the uterus, it is certain that long-standing dysmenorrhœa must eventually induce

some tissue change. In the treatment of dysmenorrhœa which is regarded as neuralgic, our principal object should be to improve the general health of the patient. This may be attempted by the administration of the various tonics—iron, quinine, arsenic, and phosphorous. During the paroxysms of pain it becomes imperative to give relief by some sedative commensurate in power to the degree of pain. Musk, camphor, asafoetida, and bromine are useful in some of the milder hysterical forms, but when the agony is intense chloral and opium alone afford relief. It is sometimes necessary to place the patient under the influence of ether or chloroform to give temporary relief to pain which has become insupportable. The local treatment consists in the application of hot fomentations to the abdomen and the use of warm douches. In some cases the treatment by massage and diet, recommended by Dr. Weir Mitchell, yields extraordinary results.

*Congestive Dysmenorrhœa* depends upon some change in the condition of the uterus itself or its appendages. In the true congestion form the pain precedes the flow of the menstrual discharge, and is relieved by its appearance. Various states of the general health may induce it such as general plethora, constipation, and impeded portal circulation. Exposure to damp and cold during menstruation may arrest the flow, and has frequently been the starting point of subsequent menstrual irregularities. The local causes are the several displacements of the uterus, chronic metritis, thickening of the uterus, and the various forms of perimetritic inflammation which restrain the natural movements of the uterus, and thus produce congestion. The treatment must depend on the condition which produces the symptom. In plethoric subjects the administration of mercury in the form of blue pill or calomel alternated with some other purgative, either saline or vegetable, will relieve the venous congestion in the pelvis and afford relief. Regular exercise and a restricted diet, if persevered in, will effect a permanent cure. When the dysmenorrhœa is due to sudden suppression of the catamenia from a chill or

catching cold, warmth and rest are the means to be employed. Warmth may be applied locally in the form of hot vaginal douches or hip baths. Rest and warmth by placing the patient in bed. The pain and tendency to inflammation call for sedatives, these may be one or other of the forms of opium, and may be given by the mouth or rectum. Morphia suppositories are always useful where there is pelvic pain and congestion. If the congestion results from displacement of the uterus, the application of a Hodge pessary replaces it in position, and allows the natural flow to proceed unchecked.

In a large proportion of cases the dysmenorrhœa results from *obstructed excretion*. There is a narrowing of the os externum with or without a projecting vaginal conical portion. The small os uteri is usually the result of congenital arrest of development, and is usually associated with a conical vaginal portion of the cervix. The obstruction to the flow of secretion from the interior of the uterus, is, in most cases, at the external os. There are cases where there is spasmodic contraction at the os internum, but these are infrequent. They are revealed by the passage of the sound. On withdrawing the sound in such cases it is felt to be seized and held by muscular contraction at the seat of the internal os. The length of the conical cervix varies; it may project half an inch, an inch, or even as much as two inches. The excessive length is generally due to acquired hypertrophic elongation. The uterine sound sometimes can only be passed through the external os with difficulty. Once inside the cavity of the cervix its onward progress to the fundus uteri is unopposed. The cervical cavity is distended by the accumulation in it of the pent up secretion of the cervical glands. Although the secretion of the cervical glands of the uterus is a thin fluid gelatinous substance it is unable to escape freely through the narrowed os externum. Now, if the small os externum is sufficient to prevent free exit of a secretion which does not clot but always remains in a fluid condition, how much more easily can it imprison the menstrual secretion which easily clots and loses its liquid form. If a conical cervix is seized by a vulsella or tenaculum and the anterior or posterior surface put on the stretch, the small round os is opened a little and some of the imprisoned cervical secretion is at once seen to escape. When the os externum is cut across an escape of a large quantity of the secretion always occurs.

The consequences of the obstruction just described take place in an ascending order above the seat of the obstruction: 1st. The cervical cavity becomes enlarged by continued distension by the pent up secretion, this aids hyperplasia of the vaginal portion; 2nd. Congestion and enlargement of the body of the uterus follow, disposing to menorrhagia, and causing uterine spasm and colic; 3rd. A similar condition of the Fallopian tubes may result; 4th. Congestion, enlargement, and inflammation of the ovaries may ensue, determining hæmatocele, or pelvic peritonitis. When the patient enters married life fresh consequences usually are added; increased congestion and inflammation of the body of the uterus, increased ovarian irritation, increased tendency to menorrhagia, acute and chronic cervicitis with leucorrhœa, abrasion of the os uteri, vaginitis, vaginismus, dyspareunia, and sterility. There is very often in such cases a history given by the patient of one or more miscarriages. On investigation it will be found that the passage of clots accompanied by menorrhagia has been mistaken by the patient for abortion. The menstrual secretion has been retained in the uterus, become clotted, and then expelled with much pain resembling an abortion. The symptoms of dysmenorrhœa from obstructed excretion are as follows: The pain commences as a heavy aching sensation before the flow appears. The seat is in the pelvis spreading to the groins and legs. As the flow appears the pain may diminish, but more frequently it assumes an expulsive character, due to the spasm from the passage of clots. The constitutional reactions are severe. Vomiting,

prostration, and pain of such a violent nature as to cause the patient to roll on the floor may be present. It is natural that the continued recurrence of such symptoms month after month end in wearing out the health and strength of the patient, and reducing her to a state of chronic invalidism. The above array of symptoms, however, is by no means exaggerated. Similar symptoms may arise from the obstruction caused by flexion of the uterus forwards or backwards. India-rubber tube, and yet this has been denied. The treatment of obstructive dysmenorrhœa lies in the enlargement of the os externum, and in the case of spasmodic contraction of the internal os by division with the metrotome or dilatation with bougies. To begin with the treatment by dilatation. It has been a common practice to dilate the cervix with sponge, or laminaria tents. If this is done it is best to apply the tent the last thing at night, and remove it early the next morning. Its effect is, however, only temporary, the cervix contracts again, and if the operation has been undertaken for sterility, it is more due to luck than anything else if impregnation occurs during the short time the cervix remains patent. The proceeding, moreover, is not without danger. Pelvic peritonitis may result. Septicæmia is often a sequel to the use of tents, especially sponge tents which are more likely to abrade the os uteri, and thus open a gate to septic absorption. Their use is not efficient, and it is not free from danger.

The old treatment by stretching the os and cervix by graduated bougies is less objectionable. The plan is to pass one bougie into the uterus after another, beginning with a small one, and going on until a large one has been passed. Each bougie is left *in situ* for a few minutes to overcome the spasm of the uterine muscles, and to dilate the cervical canal. It is then removed, and a larger size introduced; the whole operation is effected at one sitting. The time selected for this is about three days after menstruation has ceased. The operation may have to be repeated at the end of three or four months. It is usually effected without chloroform, but in some cases it is necessary to administer some anæsthetic. Dr. Godson has found the treatment by the graduated bougies generally successful. He has not often had to perform the operation more than two or three times successively on the same patient. He regards it as being less dangerous than any other means of dealing with constriction of the os uteri, or cervical canal. I think, however, the operation is open to the same objection as that of dilating with tents. It is inefficient, its effects are not lasting. This is proved by the fact that it often requires to be repeated. It is, further, tedious, and often extremely distressing and painful to the patient. The most satisfactory method of dealing with the stenosis is by incision of the external os. It is hardly ever necessary to divide the os internum. The operation may be performed by the metrotome, or by the scissors. At one time the practice of dividing the os internum with a double-bladed metrotome was common. Greenhalgh's was the pattern generally used. The instrument is a dangerous one for the following reasons: The blades are set to cut to a given depth, and then opened to that extent by a lever. It is thus clear that the knives may cut farther than is necessary, and thus do injury which is not intended. The thickness of the neck of the womb in the region of the internal os is not uniform, and so, if the knives are set so as to cut too deeply, and the cervix happens to be narrower than usual, it is easy to wound one or both of the uterine arteries. The cutting is done in the dark by automatic machinery. The single-bladed metrotomes of Aveling and Simpson are not open to the same objection. The operator sets the blade to the extent he thinks necessary, and then cuts with it in nearly the same way as he would with an ordinary bistoury. He can measure by his touch the depth of incision which he makes into the tissues. When it is necessary to divide the internal os, Aveling's single-bladed metrotome is the most convenient and the safest in its action. The blade

is set, and the instrument having been passed into the cervix, it is opened and used as a knife, whilst the cervix is steadied by a volsella. The division of the external os can be effected by the same instrument in a similar manner. In using Aveling's metrotome, it is most convenient to place the patient on her back, with her knees drawn up, and the uterus displayed by a Sims' speculum. The uterus is then easily seized with a volsella or tenaculum, drawn down, and steadied whilst the cervix is being divided. Simpson's metrotome may be used for the same purpose in a similar manner. Another way of dividing the cervix is by means of Küchenmeister's scissors. The blade which is tipped like a uterine sound is passed inside the cervix, whilst the hooked blade is opened outside the cervix, and made to cut through it on to the inside blade. The instrument is then turned round, and the other side of the cervix divided in a similar manner. By this operation only the vaginal portion of the cervix is divided, the os internum being left untouched. The after-treatment is simple. The patient should be kept quiet in bed for four days, not being allowed to leave her room until the end of the week. I am not in the habit of applying any dressings to the wound or interfering with it in any way. Some gynaecologists are in the habit of passing the sound daily for several days after the operation, in order to prevent reunion of the cut surfaces. This may be necessary after the clean cut made by the metrotome, but it is not required when the scissors has been used, because the wound is of a more lacerated and contused nature, and less likely to unite. Another means used to prevent union of the divided surfaces is the introduction of a stem pessary, vulcanite, silver, or galvanic. This is open to the objection that pelvic inflammation and septicæmia not unfrequently result. The daily passage of the sound is equally dangerous. I have seen pelvic peritonitis, followed by effusion and abscess, and even death, result from this practice in the hands of others. I have never resorted to it myself.

In the event of secondary hæmorrhage occurring after the operation, the best plan is to pass a speculum into the vagina, and clear away all the clots which may be present. The os may then be seized and steadied with a Sims' tenaculum, and the wound plugged with some lint steeped in a solution of perchloride of iron or tincture of iodine. The plug in the os uteri may be supported in its place by packing the vagina with carbolised lint. The results of this operation are, upon the whole, most satisfactory. (Traver's case.) The accidents which have been reported as having resulted from the operation have in nearly every case arisen from some imperfect mode of performing the operation, or from carelessness and neglect of ordinary precaution in the after-treatment. Sir James Simpson thought so little danger attached to the operation that he used to perform it in his consulting-room, and send the patients home in cabs immediately afterwards. Others followed his example, and it is not surprising that pelvic cellulitis, secondary hæmorrhage, and other accidents occurred, and thus brought an excellent and safe operation into undeserved odium.

The objects in view—the relief of the dysmenorrhœa and sterility—are not always attained immediately. The pain during the first or second period after the operation may be even worse than before it. This is due to the congestion and irritability remaining in some cases after the operation.

When undertaken more especially for the cure of sterility, the success is to a great extent dependent upon the time at which the operation is done. The earlier in life that a narrow os is divided, the greater is the likelihood of curing the dysmenorrhœa. Young married people anxious for children usually consult a medical man after about two years of married life. If a small os is discovered and divided at this time, the results will almost certainly be satisfactory. It is when the condition has persisted for many years, and consequent organic changes in the uterus have taken place, that it

becomes more difficult to relieve the dysmenorrhœa, and often too late to cure the sterility. The cure of dysmenorrhœa is more frequent than that of the sterility. The relief of the dysmenorrhœa alone however, is of the greatest importance to the comfort and health of the patient, and it is in the great majority of cases for the attainment of this object that she seeks advice. The sterility may not be removed although the obstruction has been, because there may be conditions in the Fallopian tubes, or ovaries which preclude impregnation. There may be old pelvic adhesions fixing the uterus, the ovaries, or tubes. Some of these conditions are beyond clinical diagnosis, and can only be recognised on the post-mortem table. Another obstacle, usually an obscure one, depends upon the condition of the husband. The wife may have been placed in favourable condition for impregnation which does not ensue.

It is objected against the operation of dividing the os uteri that it sometimes closes again. This does occasionally occur. When it does the operation may be repeated and the canal kept open by a stem pessary.

*Membranous dysmenorrhœa* results from the discharge at the menstrual periods of material, either consisting of the mucous lining of the uterus or organised tissue resembling it. The process is usually attended with pain of a severe nature. Sometimes the membrane comes away in shreds, at other times it forms a distinct cast of the uterus. The point still under debate is whether or not the membrane is the product of conception or not. As a matter of fact it occurs more frequently in married than in single women. The causes are obscure; endometritis, ovarian irritation, abortive conception being those most usually put forward. The treatment must depend upon the view taken of the cause of the disease. If a syphilitic taint is suspected, and the casts regarded as abortive decidua membranes, an antisyphilitic course of treatment may be adopted. Whether this view however is taken or not the unhealthy condition of the uterine mucosa requires treatment. The best practice therefore in any case will be to pursue a course of intra-uterine medication. One or other of the various applications to the interior of the uterus, such as fused sticks of sulphate of zinc, nitric acid, tincture of iodine may be tried. Where the above means all fail the uterus may be dilated with a laminaria tent, and the diseased mucosa carefully scraped with a curette.

This operation may, after the next menstrual period has been passed, be followed by the application of iodine twice a week to the uterine cavity with good effect.

*Ovarian dysmenorrhœa* may result from any morbid condition of the ovary. Acute or chronic ovaritis are likely to produce painful menstruation. Prolapse of the ovary into Douglas' pouch where it is pressed against the uterus by accumulated fœces is a cause. Congestion of the ovary, epilepsy, and hysteria are allied factors. The diagnosis depends partly on the history, partly on the symptoms and physical signs. If the ovary on either side can be felt on vaginal examination, tender and enlarged, the diagnosis is clear. It is the same if it is found prolapsed into Douglas' pouch. The treatment is not very clear. If an ovary is found prolapsed an effort should be made to replace it and retain it in position by a Hodge pessary. The pain should be relieved by such sedatives as the bromides, Indian hemp, camphor, and hyoscyamus. It is not wise to administer opiates and stimulants in such cases because the pain is likely to continue for years, and confirmed habits of opium or alcohol are too easily acquired. Local pain at the periods may be relieved by the application of turpentine stupes over the abdomen, mustard poultices, and blisters over the ovarian regions. Warm hip baths and tepid sedative vaginal douches may be used during the menstrual period.

In those cases where the neurotic symptoms are exaggerated, and the patient's life is one continual period of pain and suffering, removal of the ovaries may be advisable. It is likely before long that oöphorectomy will come to be recognised as the right treatment in such

cases. Just as ovariectomy is performed for the removal of ovarian tumours, so will oophorectomy find legitimate application in obscure and persistent cases of ovaritis.

A CASE OF  
GANGRENE OF THE HAND, WITH RE-  
MARKS—SURGICAL AND ETHICAL.

By VERNON W. RUSSELL, L.R.C.S.I., &c.,  
Surgeon County Tipperary Infirmary ;

AND  
DANIEL MOLONY, F.R.C.S.I.

The following case is, we believe, of ethical as well as surgical importance. The subjoined article, printed in handbill form, has been scattered broadcast throughout the land. Apart altogether from considerations of self-respect, and having regard solely to the dignity of our profession, it is, of course, out of the question that we should attempt to meet the writer with his own weapons. We could only do so by descending to what we would consider the level of professional advertising, and in fact circulating a similar production to his. This we decline to do. We prefer to lay the case in all its bearings before our professional brethren. We shall first give the handbill to which we have referred.

*A Case of Severe Injury to Arm.*

By THOMAS LAFFAN, M.R.C.S., M.R.C.P., &c.

The publication by Mr. Bellamy, Surgeon to Charing Cross Hospital, in the *Lancet*, of May 2nd, 1885, of a case of alarming arterial hæmorrhage from a wound at the bend of the elbow, which he treated by compress and tight bandage, both of which were kept on eight days, suggested to me the publication of a similar case.

Like his, it presents no points of interest arising out of novelty of practice; but, it has an ethical aspect, which furnishes matter for consideration for every man of honour.

On the evening of Sunday, April 12th, at 8 p.m., I was called to see a male, æt. 30, whom I found in a dinky hole in a semi-fainting condition, surrounded by an awe-struck group, having nearly bled to death from wounds in the arm which had been just inflicted by a ferocious animal. These were situated in the middle third of the right arm, the more serious one being on the inner posterior aspect of the limb. The blood flowed in a continuous and fearful stream, while it was being examined. I at once applied a compress and bandage. The bleeding at once ceased. The next morning at 9.30 a.m., the patient complained of pain, and I loosened the bandage, when the recurrence of the bleeding obliged me to re-apply it as tight as before. On this occasion the bandage proved insufficient, and oozing continued; I resolved to cut down on the wounded vessel; and, as, for this purpose, a competent administrator of ether was necessary, I telegraphed for Dr. Heffernan, of Killenaule, who is one of a number of gentlemen that favour me from time to time with their presence and valuable assistance at operations in the hospital under my charge. Pending his arrival, however, I was so satisfied that gangrene had commenced, that I considered it to be now a matter of amputation. Dr. H., on his arrival, coincided with my view as to the necessity for amputation; whereupon it was suggested that two Cashel surgeons should be called in. I gave a ready assent, though I had ample experience of the inimical feelings of both towards me. When they arrived they looked at the arm, and then proposed amputation.

At this point, let the reader pause for a moment and reflect that as the bandage was of the ordinary roller width, the whole of the limb was, for the purpose of determining the question of gangrene or no gangrene, as effectually open to view as need be, without stripping off a single turn of the roller.

The entire matter was then put, in all its bearings, before these gentlemen. I urged that the object of amputation was to sacrifice a part, in order to save the whole, and, in some instances, even to sacrifice it merely to preserve the whole from a strain that might permanently enfeeble the constitution. When the bandage was removed, little blood came for it had by this time been permanently arrested. Finally, both opposed the amputation. This ended the matter; for in the last surgeon called in medical rules vest the control of the case.

The next week was industriously spent by them in proclaiming *ad urbem et orbem* that I wished to amputate where there was no necessity, that no gangrene existed, and that they would save the limb to the very nails. My attendance terminated 19th of April, but I had remained long enough to satisfy myself that the unhappy patient was attacked with blood poisoning, and that he should now have to face all those mischiefs, and that severe constitutional strain, against which amputation has been devised by our art as a remedy. Mystery itself is no name for the secrecy in which the subsequent progress of the case was shrouded. This much, however, of what has transpired I shall state—(1) That the hand has actually dropped off; (2) that the patient has been at death's door; and (3) that the forearm is, as no surgical reader requires to be assured, in a condition which will demand further amputation.

I need not say one word to my surgical readers as to what the outcome of this case will be. The form of gangrene here was certainly calculated to deceive the uninitiated, for it was of that dry variety which proceeds from arterial failure, and which differs so materially from that due to venous strangulation. Moreover, the palm of the hand retained for a long time its cutaneous sensibility, and this was calculated to throw off their guard parties unacquainted with the anatomical and physiological conditions pertaining to its nervous supply. These two surgeons, who were unable for a long period to recognise the presence of gangrene, are now seized, some wags tell me, with a great anxiety to give me some lessons in bandaging. One of them is good enough to say that I should not have bandaged at all, but that I should have trusted to finger compression. That could be carried out in a suitable case, only by a number of skilled medical students, and in the great Charing Cross Hospital, where they have such, they employ, as is clear from the article quoted, my treatment, and none other.

The second surgeon, who is animated by an equal benevolence, kindly alleges that I ought to have bandaged from the fingers. I shall simply quote from two letters from Mr. Bellamy, one of the first surgeons in London, an Examiner in the Royal College of Surgeons, England, and the occupant of quite a number of distinguished offices. I do not know whether my *confrères* are merely funning on this point; but, as it is possible that one individual might be found who would take them in a serious vein, for the benefit of such, as well as for the enlightenment of my very honourable *confrères*, I now give the quotations.

The first letter was in reply to one of mine to Mr. Bellamy, containing full details of this case. I asked him did he bandage *his case* from the fingers up? His reply is as follows:—

"17 Wimpole Street, London, W.  
May 12th, 1885.

"DEAR SIR,—In answer to your note I certainly did not bandage from the fingers, and, I cannot conceive anything which would be more disastrous to the treatment had I done so. Such surgery is reprehensible in the extreme."

*In a further letter, dated June 8th, he writes:—*

"You are perfectly welcome to make what use you like of my letter, and should make them pay smartly for what they have done; I shall be very pleased to come over. If you proceed against them you are sure to

win. I have been just also elected Examiner in Surgery in Owens College (the Victoria University), and I should expect to get the treatment you adopted from a candidate."

Cashel, June 12, 1885.

For the credit of the profession, of which, strange as it may seem, the author of the handbill is a member, it is to be regretted that such a production should have been circulated. It is still more to be deplored that its contents are mainly untrue and utterly misleading. We at first resolved to treat the *brochure* with the passive contempt it deserves, but inasmuch as it publically misrepresents us and openly assails our professional characters, we have thought it advisable to take more notice of it than that to which its intrinsic insignificance might seem to entitle it. We shall deal with the assertions which it contains in as brief a manner as possible.

(1.) *There was not dry gangrene.* The gangrene of the hand was of the kind which results from obstruction to the venous circulation; as for example in the case of excessively tight bandaging. We may here mention that in our present case the compress consisted of *two florins and a shilling*. The reader will hardly be surprised to hear that the portion of the arm exactly corresponding to the compress (which by the way was wrapped in a piece of calico) subsequently sloughed almost to the bone.

(2.) We have to contradict the statement that "the palm of the hand retained for a long time its cutaneous sensibility." When we first saw the case there was *complete loss of sensibility* from the bandage to the tips of the fingers.

(3.) The patient *was not* attacked with blood-poisoning. There was never the slightest symptom of any such complication.

(4.) The patient *was not* at "death's door." His highest temperature was 102°, and this was only immediately subsequent to the torture of the "metallic compress."

(5.) The hand *did not* drop off. We amputated it with the lower portion of the ulna when in a state of hopeless gangrene.

(6.) The forearm *is not* in such a state as to require further amputation. It is on the contrary progressing rapidly and favourably.

(7.) The room in which the patient lay *was not* a "dingy hole," and even if it were, the patient's residence, a large and roomy house is distant only about thirty yards.

Now, the simple truth of the matter is this, we were called to see the patient and to consult with Dr. Laffan, who had just proposed amputation. We found the arm enormously swollen, cedematous, and insensible to the finger tips, with a bandage and compress literally *buried* in its middle third. Dr. Laffan, alleging that the brachial was wounded, and that the terrible condition of things before us arose from arterial failure, urged amputation at the shoulder. This we opposed on the ground that the bandage and compress seemed to be the cause of the mischief, and that by their removal we might still hope to save the arm, or at least some portion of it. Fortunately our counsel prevailed. The compress and bandage being removed, to the great relief of the patient, we wrapped the limb in cotton wool, restored the circulation, so as to feel pulsation in the brachial, and subsequently in the radial arteries, and finally succeeded in saving the arm and forearm, with the exception of the lower portion of the ulna. From the beginning we doubted the possibility of saving the hand, which we were eventually obliged to amputate.

Such is the history of a case, into which, through no fault of ours, a personal element has been introduced. We shall now consider briefly the surgical principles involved, which although of extreme simplicity are yet of the utmost importance. We have always known that the recognised mode of dealing with wounds of the

brachial artery is to tie the vessel immediately above and below the wounded point. When ligature is impracticable or undesirable, as in the case of diseased arterial coats in an old subject, or when the vessel wounded is a vein, or when the hæmorrhage arises from small arterial branches we have always understood that the rule of surgery is to apply a compress and bandage, taking great care to also *bandage each finger, the hand, forearm, and arm up to the seat of injury*. The consequences of neglecting this latter precaution are familiar to the merest tyro in minor surgery. They are acute pain, obstruction to the venous circulation, cedematous swelling, and finally mortification or gangrene. These we believed to be surgical truisms, immeasurably removed beyond the reach of discussion. However, the question has been raised, it has been *practically* raised. Under such circumstances we thought it to be our duty to ascertain beyond doubt the views of eminent and representative surgical authorities on the matter. To those gentlemen who have favoured us with communications we beg to return our sincere thanks.

Mr. Hamilton, of Dublin, Fellow, Ex-President, and Professor of Surgery in the Royal College of Surgeons, writes:—

"MY DEAR DR. MALONY,—In reply to your inquiry as to the treatment of wounded arteries, I beg to say that it is the imperative rule of surgery to tie the vessel both above and below the point from which the bleeding comes. If the original wound is too small to admit of this being done satisfactorily it must be carefully enlarged. Should the bleeding come from a number of small arteries or a vein it can easily be controlled by the finger of an ordinary assistant. *Each finger should then be separately bandaged, and the entire limb up to the wound: on this a graduated compress with moderate pressure will command the bleeding without risk of strangulation or gangrene.*—EDWD. HAMILTON."

Mr. Wheeler, of Dublin, Fellow and Ex-President of the Royal College of Surgeons, Surgeon to the City of Dublin Hospital, &c., writes:—

"DEAR DR. MALONY,—With reference to your queries, I have to inform you that in the case of a wounded artery I would tie both ends of the vessel, and if necessary enlarge the wound to do so. You have alluded especially to wounds of the brachial artery. There can be no hesitation in stating that the above course would be the correct one to adopt. In the case of venous hæmorrhage from the arm would apply a compress over the wound, *and bandage the fingers, hand, and forearm up to the seat of injury*. Such is the correct and recognised surgical treatment.—I am, yours very truly, W. J. WHEELER."

Dr. Heron Watson, Fellow and Ex-President of the Royal College of Surgeons of Edinburgh, Surgeon to Her Majesty the Queen in Scotland, &c., writes:—

"Undoubtedly the great axiom about bleeding arteries is to tie the bleeding point above and below the opening of the arterial tissues."

Referring to small punctured wounds of the brachial artery, he continues:—

"A graduated compress was frequently adopted, and certainly sometimes with a successful result. The graduated compress was applied with a 'figure of eight' bandage, and then *each finger, the hand, and forearm*, supported by a roller bandage to obviate venous congestion and œdema."

Mr. Ormsby, of Dublin, Fellow of the Royal College of Surgeons, and Surgeon to the Meath Hospital, referring to those cases of simple penetrating wound of the brachial, in which the compress and bandage treatment would appear suitable, writes:—

"I would apply a pad over the bleeding point, and *bandage each finger, hand, and forearm* to above bleeding point."

Dr. Macnaughton Jones, of London, says:—

"The rule I would follow in the case of a wounded

brachial artery in the part mentioned (middle third) would be to cut down and tie the vessel above and below the wounded point."

Professor Pearson, of Cork, writes:—

"I have not the slightest hesitation in saying that, provided the coats of the artery be fairly healthy I should prefer ligature of the artery above and below the wound, with division of the intervening portion (if that is not already complete) to any other mode of treatment."

Referring to cases in which the arterial coats are too diseased to bear ligature, he goes on to say:—

"I would apply a bandage to the limb from the fingers up to the wound, and then apply a compress and bandage to the latter, and keep the limb well elevated."

Finally, Mr. Bellamy (whose attitude in the matter, judging from his letters, would appear to be subject to variations) now writes:—

"My remarks as to bandaging fingers referred to my own case in *Lancet*."

In Mr. Bellamy's case we may here remark that the ulnar was the artery wounded. After eight days of compress and bandage treatment, Mr. Bellamy was obliged to enlarge the wound, and tie both ends of the injured vessel (see *Lancet*, May 2, 1885.)

We now bring to a close the discussion upon which we entered with extreme reluctance. We have endeavoured to present the matter to our readers in as fair and honourable a manner as possible. We have given Dr. Laffan's handbill side by side with our own comments thereon. We have, in fact, submitted the question in all its bearings. We now lay the case with confidence before the high court of our professional brethren.

## HISTORY OF THE PROGRESS OF LARYNGOLOGY FROM THE EARLIEST TIMES TO THE PRESENT.

By GORDON HOLMES, M.D.,

Physician to the Municipal Throat and Ear Infirmary, London;  
Consulting Physician to the Sheffield Ear and Throat Hospital.

Il importe beaucoup de connaître l'histoire de la science à laquelle on s'attache.—Boerhaave.

### EPOCH I.—THE PRE-LARYNGOSCOPIC AGE.

(Continued from page 51.)

SECOND PERIOD.—From the death of Hippocrates to the death of Galen.—About 357 B.C. to 200 A.D.

DURING the first century of this period the orthodox medical science of the former age gradually extended itself beyond the monopoly of the Asclepiadæ, and then broke through the bonds of their narrow traditions and dogmatism. A new and less biased apprehension of the subject arose, and an ardour for further research, kindled by Philinus and Serapion (36) glowed in the minds of the rising generation of observers. A medical school of celebrity was founded at Alexandria, of which Erasistratus and Herophilus were the most prominent members, and they, discarding prejudices, found means to study anatomy on the human body. (37) With such zeal did they prosecute their inquiries that they are even said to have dissected criminals alive. (38) In the meantime, owing to the reduction by Roman conquest of almost all the previously independent countries under one nationality, science became widely disseminated, and medicine was practised with an equal degree of enlightenment in numerous distant localities. Observations being thus made from several different standpoints a number of different sects arose, at variance with each other respecting certain doctrines in pathology and therapeutics. (39)

Owing to the foregoing circumstances the medical literature of this period became extensive, and no longer confined to the Greek language. Most of the writings, however, are lost, and there is little or no contemporary work, except

that of Aristotle, to represent the first four centuries. But for the last centuries there is ample material to obtain a comprehensive view of the progress made in the copious essays of Celsus, Aretæus, Rufus Ephesius, Cælius Aurelianus, and in the encyclopædic treatises of Galen.

*Anatomy.*—Aristotle's (384-322 B.C.) knowledge of human anatomy is not greatly in advance of that of the Asclepiadæ, his immediate predecessors. In his treatise on natural history, however, produced about 330 B.C., he frequently mentions the larynx (40) or pharynx (41) (using both names as synonymous) and recognises it as a distinct part of the windpipe, and as having a cartilaginous structure. He describes none of the parts of the organ except the epiglottis, the absence of which he notices in birds. (42)

The anatomical discoveries of Erasistratus and Herophilus, who lived about the beginning of the third century, B.C., were numerous and important, but no record of their labours, except a few quoted fragments, is preserved in their own words. To them, however, we may safely refer the great advance manifested in that branch of science by the writers at the end of this period, who in knowledge of the leading facts of anatomy were almost abreast of the present day. To Erasistratus is attributed the joining of the word *trachea* (rough) to *arteria*, so as to distinguish the windpipe from other arteries. (43)

The medical miscellany which passes under the name of Rufus Ephesius, who flourished about 100 A.D., contains two short treatises (44) which are the earliest exposition of anatomy as extended by the work of the Alexandrian school. But these are mere tracts giving outlines of the subject, though indicating that the brain, muscles, and nerves, &c., had been well observed. The study of anatomy on the human body seems to have lapsed out of practice, as the directions recognise only the dissection of apes, pigs, &c. The nerves of the neck are referred to vaguely, rendering it probable, however, that the recurrences had been noticed as well as the vagi. The principal passage is:—"Formerly they called *carotids* (*stupefiers*) the vessels (passing) through the neck, because on their compression the persons became lethargic and voiceless, but now it has been perceived that this affection is not of the arteries, but of the sensitive nerves existing near, so that should the name be changed, it would not be wrong." Rufus also describes the movements of the larynx in deglutition.

Passing thus rapidly through nearly five centuries, we find to Galen (about 130 to 200 A.D.), and in his works we find an ample reservoir into which, amidst much of his own, all the medical erudition of the preceding centuries flowed in a liberal stream. Turning from the obscure and indefinite allusions of previous authors, we appear to encounter the larynx as all but a new creation in the accurate and nearly complete descriptions of its parts and functions furnished by Galen. Whilst presenting his elucidations the writer remarks on the scant attention paid to the structure of this organ by former observers. Galen has, therefore, the claim, full and indisputable, to be regarded as the founder of laryngology.

Galen describes (45) the larynx as composed of three cartilages, exclusive of the epiglottis. He explains that the thyroid had already been named from its shield-like form (*θυρεω ειδος*), and also the arytenoid, supposed to be a single piece, from its likeness to a pitcher or ewer (*ἀρυταινω ειδος*), but that the third has no name (is *ἀνώρυστος*, that is, innominate), though resembling a ring (*κρικο ειδος*). The incomplete rings of the trachea were also well observed by Galen. He goes on to enumerate the muscles, mentioning their attachments and actions, but without giving them their present names. He divides them into an intrinsic and an extrinsic set, of the first three pairs, corresponding to the thyro-hyoid, sterno-thyroid, and inferior constrictor of the pharynx, and of the second set five pairs, viz., the—1. external, and 2. internal fibres of the crico-thyroid, 3. the lateral, and 4. posterior crico-arytenoids, and 5. the thyro-arytenoids. He also mentions the arytenoid muscle, but regards it as too insignificant to be separately classed. The pneumogastric nerve, (46) was well known to Galen as the sixth cranial nerve, and he gives a good general description of its distribution. To the spinal accessory and superior laryngeal he alludes very vaguely as branches, but he describes the recurrences (47) minutely, recording carefully the difference in origin and course of the right and left nerves.

Galen bestowed the name of *glottis* (tongue) on the vocal bands, which he thus describes:—"In the interior of the

larynx is a body which in substance (48) and shape is similar to nothing else in the whole animal.....It is, in fact, like the tongue of a pipe, (49) especially if regarded from above and below." He also notices the ventricles, but does not seem to distinguish the ventricular bands from the body he calls *glottis*.

*Physiology*.—Aristotle thought deeply over the question of voice production, but his ignorance of the parts of the larynx prevented his coming to any definite conclusion. His clearest notions on the subject may be summed up in one quotation. (50) "No animal," says he, "emits sound by any other part except the pharynx (meaning the larynx). The voice and the larynx utter vowels, the tongue and the lips consonants."

The reference to the physiology of the laryngeal nerves, by Rufus, has already been given. He also mentions that the great division of the nerves into motor and sensory had been made by Erasistratus and Herophilus, but that many still entertained doubts of its validity.

Galen separates the intrinsic muscles of the larynx into those which open and those which close the larynx. The latter act he states to be accomplished by the fifth pair (thyro-arytenoids) alone, assisted, however, by the arytenoid muscle. He speaks of the laryngeal nerves as motory only, and thinks that the muscles closing the glottis are, for some physiological reason in connection with retention of the breath, supplied by the recurrens from *below*. He mentions (51) that if one of the sixth pair (vagi) is compressed in a noose the animal is at once rendered mute, and refers (52) to the case of a boy who was rendered dumb by an injury to the nerves during an operation on the neck (the "tearing out" of a *struma*).

Galen theorises (53) with great justice and force on the disposition of the glottis, necessary for the production of sound and for holding the breath. "As the pipe," he argues, "would be useless without the tongue (the *reed* as it is now called) . . . so voice could not be formed unless the passage is narrowed. For if the whole should lie widely open, the first two cartilages being released, and at a distance from each other, and the third open, voice could in no way be produced; for if the breath pass out gently, expiration is made without sound; but should it be sent forth in the volume suddenly and with vehemence, what is called a sigh occurs. In order, however, that the animal may emit voice it requires, no doubt, the motion of the breath, but none the less the narrowing of the channel in the larynx; not a simple narrowing, but one which can by degrees be constricted and by degrees relaxed. Such is what the body we are dealing with effects accurately, and hence I call it the glottis or tongue of the larynx. But this body of the glottis is not only necessary to the organ of voice, but also to what is called holding the breath . . . to which action the nature of the aforesaid glottis contributes not a little; for to effect the said purpose the parts of it on the right and on the left approach, so as to fall together accurately and close the passage. But should a small portion be left unclosed, not even this, as being unforeseen, has been disregarded by nature, who has worked an opening on each side of the glottis and placed in continuity with it a cavity within by no means small. When the passage out is blocked, the air, being confined in a narrow space, is diverted forcibly towards the sides, and opens the mouth of the aperture of the glottis, which hitherto had been closed by the folding together of the lips. The cavities in the glottis of the larynx being thus filled with wind it is of course necessary that the swelling so produced should bulge towards the passage of the breath, and shut it with exactitude, even if a small part had previously been left open." (54) These arguments convey the impression that Galen conceived vocal sound to be produced by a joint action of the vocal and ventricular bands. It is also clear that he believed alterations of voice in pitch or loudness to depend on variations in the width or area of space between the vocal bands.

*Pathology*.—Notwithstanding the great progress made in the anatomy and physiology of the larynx we shall not find that the pathology of the organ advanced with an equal step. In this field the impossibility of seeing the part affected, and the non-practice of post-mortem examinations fully blocked the way. We may note here that Asclepiades, of Bithynia, who practised at Rome about 100 B.C. is said to have divided diseases into the two great classes of *acute* and *chronic*.

The first author we meet in this department is Celsus, a Latin writer (flourished about 1, A.D.), who treats of cynanche much in the old Hippocratic terms, without showing any distinct advance in apprehension of throat diseases.

Next we come to Aretæus (about 70 A.D.), of whom little more can be said. He draws, however, a distinction between *cynanche* and *synanche*, (58) limiting the latter term to what we may assume to be acute affections of the larynx. Some further observation is also indicated in one or two passages, respecting elongated uvula, for example, of which he says:—(59) "For a tickling of the artery (windpipe) is caused by the membrane, and sometimes a little of the moisture drops into it unperceived, on which they cough." And in speaking (60) of ulcers on the tonsils his remarks are suggestive of laryngeal diphtheria (croup), e.g., "There are peccant ulcers which are broad, hollow, and foul, invested with a white, livid, or black concretion. . . . If they spread to the thorax by the artery they suffocate on the same day."

Cælius Aurelianus, a Latin writer, who was probably contemporary with Galen, makes four classes of throat inflammation, (61) viz., *cynanche*, *synanche*, *para-cynanche*, and *para-synanche*, the compound terms implying the external affections corresponding to the two first. He is also the first to describe symptoms which indicate sub-acute or chronic catarrh of the mucous membrane of the larynx, i.e., a deficiency of voice (*voicis amputatio*) including hoarseness and aphonia, which arises from excessive shouting, cold, &c.

Here, as in other branches of our subject, we find that Galen, in theory at least, almost treads on the heels of the modern laryngologist. His actual observations of laryngeal disease do not seem, however, to go much beyond previous writers. Like Cælius he reckons four kinds of cynanche, but he also mentions (62) two cases of young men in whom he diagnosed ulceration of the larynx from the ejection of small quantities of purulent and sanious sputa, and also in one instance of a membranous flake. The larynx was further indicated as the seat of disease by troublesome and painful sensations in eating and swallowing referred to the part.

Passing by these experiences without more lengthened notice we come to two important passages which claim to be reproduced. The first relates to chronic catarrhal laryngitis, and appears to have been reasoned out by the aid of semeiological observation on alterations of voice. After alluding to the mucous membrane ("pellicle") lining the larynx and trachea and its continuity with that of the fauces he remarks:—(63) "Loss of voice, that is inability to speak, follows many causes; sometimes a chronic flow from the head, at others even abscess of the lungs and phthisis." It also occurs in those who have been injured by great and protracted shouting, and have not been properly cured or had the diathesis which engenders it. In the same way a hoarseness arises, but more especially from inspiration of cold air and moisture, &c. Aphonia and hoarseness are therefore affections of the same kind. These evils differ, however, by degrees of magnitude in their relations to each other. Hence when the vocal organs have been violently and obstinately steeped in moisture aphonia supervenes, if moderately affected, hoarseness. When I say the vocal organs, understand the artery, larynx, and pharynx. Such persons, therefore, as have specially injured their voice by excessive vociferation suffer from a malady similar to that which affects the hands, thighs, loins, spine, and muscles, after being subjected to great exertion. Now, some of the teachers of gymnastics call such an affection *inflammatory lassitude*. Thus in the artery the internal pellicle, tunic, or whatever it may be called, being struck by the breath passing out in violent declamation enters into an inflamed state, and much more so if a certain sharpness is added to the intensity of voice. But in the case of the larynx besides this shock there is also an injury of the energy of the muscles that move it which increases the disease."

The second passage (66) reveals theoretically a system of laryngeal pathology springing from etiological considerations as to changes or loss of voice. "Moreover," he states, "I wish you to understand that voice and speech are not the same thing, for voice is the creation of the vocal instruments, and speech of those for speaking, of which the tongue is altogether the chief, but the nose, lips, and teeth assist not a little. Thus the vocal instruments are the larynx and the muscles moving it and the nerves from the brain which give them power. Hence, if the muscles which

close or open the larynx are rendered immobile, the person becomes altogether aphonic, but should they be moved with difficulty or palpitate or tremble, the voice will be affected according to the nature of the lesion; similarly should they act in a spasmodic or jerky manner. Should they be weak in their power, through an affection of themselves or of the nerves moving them, they will make the voice obscure and small. But should any other of the muscles that move the larynx suffer in any way, voice will indeed be affected, but by a slight lesion, and the person will be neither altogether aphonic, nor will have properly a small voice. But as amongst the muscles moving the larynx, those opening and closing it are the principal, so of the vocal nerves are those called *recurrent*, which are themselves part of the sixth conjugation (*vagi*) of nerves arising from the brain, like the others which also have their origin there. They differ, however, from those because they are not given off in the neck, but after the main trunk has arrived in the chest. Thus there is no surgeon so awkward as to sever willingly the whole sixth conjugation, but the recurrent nerves are sometimes cut through unskillfulness. It happens indeed occasionally in great wounds of the trachea, that one or other is incised. In surgery, also, when affected with great cold they impede the voice until being warmed they recover their natural temperature. Moreover, it occurs that the voice is injured not a little in clearness and volume when the pharynx cannot be contracted by its muscles. Likewise when the tunic common to the pharynx and larynx is steeped with much moisture. And everybody knows that for the same reason catarrh can make the voice hoarse. Violent shouting similarly affects the voice, as it engenders a malady like inflammation of the tunic aforesaid, and of the laryngeal muscles. But it is evident that when the internal muscles of the larynx are inflamed the disease is *cynanche*, which simultaneously injures voice and respiration, and doubtless all abnormal tumours whether they arise in the air-passages or compress them from without. Thus also the gullet when inflamed so as to press on the tunic of the trachea where the sigmoid extremities of its cartilages are joined, and luxation of the cervical vertebrae forwards. Hence all maladies of this kind touch the voice." From this point the author proceeds to dissert on the state of voice in general diseases, such as chest affections, apoplexy, &c., and in peroration refers to his last work on voice for further discussion on all local modifications, morbid and normal.

*Treatment.*—During this period treatment proceeded very much on the old Hippocratic lines, but a great increase seems to have taken place in the element of the materia medica, and the various articles of the pharmacopœia were carefully described, classified, and their combinations enumerated by Dioscorides, Scribonius Largus, and Galen.

The only signal advance we have to chronicle relates to the first suggestion of opening the windpipe for the relief of dyspnoea in *cynanche*, a matter which soon became involved in much controversy. This operation originated in the mind of Asclepiades, (67) about 100 B.C., but there is no proof that he actually performed it. He seems, however, to have endowed it with a distinctive name, viz., *pharyngotomy* or *laryngotomy*, (68) and must have drawn much attention to it by his arguments in its favour. The earliest allusion to the operation is found in Aretæus, who gives (68) his opinion of it in the following dubious language:—"Those who for the relief of suffocation are accustomed to cut the artery for the breathing, do not seem to have made the thing trustworthy by practice. For the heat of the phlegmon becomes greater from the wound and adds to the suffocation and cough. But, on the other hand, if this danger should be escaped, the lips of the wound do not unite as they are both cartilaginous and unhealable."

More than a century after Aretæus, section of the trachea was still a subject for emphasised discussion and Cælius Aurelianus (69) refers to it at some length, but in terms of the greatest disfavour. "Asclepiades," says he, "approves making that division of the artery on account of respiration, countenanced by our predecessors (which they call *laryngotomy*), erring in many and different ways. For everything that is sharp and attenuating inflames the humor. . . Moreover section of swelled parts is most injurious and dangerous" Further on he characterises the whole matter as a fabrication. "The operation," he urges, "is fabulous, and one which has been handed down by none of the ancients, but is affirmed only in the unstable and rash invention of Asclepiades." Proceeding in this strain he speaks of it as "so great a crime,"

and even condemns Themison, the founder of the *Methodici*, his own sect, for allowing that it might be resorted to with propriety in acute diseases without fever. Cælius gives especially lengthy details as to the treatment of *cynanche*; he is much less in favour of bleeding than Hippocrates.

Much attention was paid to the class of remedies called *arteriaca*, used for expectorants, in hæmoptysis, &c., and comprising almost all employed at present, viz., squill, turpentine, styrax, tragacanth, myrrh, horehound, poppy-heads, &c. Galen is particularly full in his account of them. (70) Expectorants made up in small masses the size of a bean, to be held under the tongue and swallowed in slow dissolution, were termed *hypoglottides*. One or two examples of the *arteriaca* recommended by Galen may be given:—

"For ulceration of the trachea, and further, for those who have to strain the voice, &c., from Lysias—R. Of saffron myrrh, juice of the sweet radish, frankincense, cassia, each ʒij.; of pepper, gr. xxiv.; of Cretan wine (*passum*), three pints; of Attic honey, six wineglassfuls. For use."

"A hypoglottis of Scribonius Largus for loss of voice—R. Of saffron, turpentine, each ʒij.; of the Illyrian iris, ʒvi.; of tragacanth, ʒviii.; of pepper, gr. cccx. Compound with honey and turpentine boiled together. The size of a Pontic nut to be used under the tongue."

Galen advises (71) ulceration of the trachea to be treated by applying externally "drying remedies" (astringent?), so that cicatrization may be favoured. At the same time the patient is to be kept supine holding in the mouth a suitable *arteriac* "so as to let it flow gradually into the trachea." He asserts that he has cured "not a few" cases in this way, convalescence being established afterwards by change of air and asses' milk. Of opening the trachea he merely remarks, (72) "Asclepiades proposed, as a last resource to prevent suffocation, to incise the windpipe at its upper part."

Aretæus (73) recommends insufflation of powders through a tube in throat diseases.

(66) Hence regarded as the founders of the sect called *Empirics* or *experimentalists*.

(67) Galen de Uteri Dissectione.

(68) Cælius, De Arte Medica, c. 1.

(69) Besides the *Empirics* there were the *Dogmatists*, who regarded the Hippocratic writings as a final authority, and the *Methodists*, who compromised with both sides.

(40) *Historia Animalium*, l. 12, 16; ii., 17, iv., 9.

(41) De Partibus Animalium, iii., 8.

(42) De Respiratione, c. 11, &c.

(43) Aulus Gellius, xvii., 11.

(44) Entitled "De Apellationibus" and "De Anatomia Partium Corporis Humani." They are clearly of different authorship, as in the first the word *pharynx* is restricted to the fauces and in the second applied to the larynx.

(45) De Usu Partium, vii., 11, et seq., xvi., 4. Also in Oribasius, *loc. cit.*

(46) De Dissectione Nervorum, c. 10.

(47) De Usu Partium, c. 15.

(48) In the pig the vocal bands are of a peculiar adipose tissue. Galen's anatomical knowledge is drawn from dissection of pigs and apes.

(49) That is an *obol*, not a *stute* in the modern sense.

## THERAPEUTICAL HINTS.

By JOHN W. MARTIN, M.D.,  
Sheffield.

THE following is an excellent lotion for subduing inflammation, and reducing the oedema of the inflamed parts:—

R. Tr. opii camph. co., ℥ij.;  
Tr. tolutani, ℥ij.;  
Liq. plumbi diacetat, ℥iv.;  
Glycerine, ℥ij.;  
Aqua, ad., ℥xxx. M.

A piece of lint, or old linen, to be well wetted with the lotion, and to be applied to the inflamed part. The wetting to be repeated at frequent intervals.

Internally, it is useful to combine the following mixture with the use of the foregoing lotion:—

R. Potass bicarb., ℥iiss.;  
Tr. nucis vom., ℥xl.;  
Ferri am. cit., ℥iiss.;  
Sp. am. aromat., ℥iiss.;  
Aqua, ad., ℥viiij. Liq. M.

“℥j. three or four times a day.”

I have found this treatment especially useful in those cases in which intense inflammation in the arms follows re-vaccination.

## Clinical Records.

### NETHERFIELD FEVER HOSPITAL, LIVERPOOL.

#### A Case of Epigastric Abscess.

Under the care of ROBERT S. ARCHER, B.A., M.B.,  
M.Ch. Univ. Dub.,  
Physician to the Hospital.

THE following case may prove not unworthy of being placed on record, as it seems to me to present some features of interest. It is one of those cases which occasionally are sent into a fever hospital as suffering from some form of essential fever, but in which, after close investigation and a short period of observation, the pyrexial symptoms are found to depend on some local inflammatory mischief, or at all events, on some cause that cannot be placed in the category of the so-called specific fevers. Although there was not much difficulty in pronouncing that the patient was not suffering from the disease she was supposed to be affected with when sent to hospital, yet there was considerable doubt as to the real nature of the case, and on this point I may say that I have not come to a conclusion at all satisfactory to my own mind. It is to be hoped that after the details of the case are related some member may be able to cast a gleam of light to illumine its obscurity. My thanks are due to Dr. Oldham, our late able resident medical officer, for his valuable assistance in keeping the clinical records, from which the following account is taken. The temperature of all cases treated at Netherfield Fever Hospital is taken six times in the twenty-four hours, but in the following record the maximum and minimum temperatures alone are given as being sufficient to indicate the course of the symptomatic fever.

A. M. S., a female domestic, æt. 35, was admitted to Netherfield Fever Hospital, on Nov. 22, 1884. The certificate of admission stated that it was enteric fever she was suffering from. The history procured from the patient was to the effect that she had been affected with *malaise* for about a week. Two days before coming to hospital pain in the abdomen and right side, vomiting, and rigors suddenly set in. The pain had continued since. There was no diarrhoea nor epistaxis. She stated that she had always more or less experienced uneasiness in the epigastric and hepatic regions. This had the effect of preventing her from “tight-lacing.”

*On admission.*—Pulse 136; resp. 30; temp. 100.5°, running up at 7 p.m. to 102.2°. Tongue dry in centre. Aspect and conjunctivæ clear, pupils normal. There was a malar flush. Pain and tenderness on pressure in the right hypochondriac region. Liver dulness extended nearly two fingers' breadth below the costal margin. The base of the right lung afforded a dull note on percussion, and there was absence of respira-

tory murmur here. A poultice was ordered to the right side, and a simple enema administered.

Nov. 23rd.—Pulse 120; temp. ranging between 99.7° and 101.4°. She was reported to have slept fairly, and the pain in the side was not so constant. Still tenderness in right hypochondriac region. No cough, but a complaint of “catching of breath.” She passed one more motion. She was ordered a little hydrochloric acid and spts. æth. nit. in infusion of gentian, milk diet, and ice to suck.

24th.—Pulse 116; temp. ranged from 99.43 to 100.4°. Tongue moist, she appeared better. Pain not so severe, the “catching of the breath” had gone, and menstruation commenced. For the next four days there was nothing of importance to note. The extremes of temperature for this period being 101.8° at 11 p.m. on 25th, and 98.4° on 27th at 7 a.m. From this time the temperature began to rise gradually, and reached 101° at 7 p.m. On 28th pulse varied from 112 to 120. Tongue became dry in centre again on 28th.

29th.—Pulse 120; temp. 99.5° to 101.4°; tongue cleaner; respiratory murmur to be heard faintly, and percussion note somewhat clearer over right base. Abdomen soft and not tender. For several days the bowels have been irregular, and there has been considerable thirst.

December 1st.—Pulse 112-122; temp. 101° to 102°. Dulness and absence of respiration over inferior third of right lung. Sub-crepitant râle heard at end of inspiration over left base, percussion note normal, has occasional cough. In the evening the skin was moist, and there was slight general abdominal tenderness. The next day there was a slight fall in the average pulse rate, the temperature also assuming a lower range (99.8° to 100.4°). There was vomiting in the evening, the general abdominal soreness persisted, and there was loose motion. The medicine was changed to quin. sulph. gr. 3; acid bromohydric, m. 15; tinct. digitalis ℥10, and spts. chlorof., ℥15; in a little water, every four hours.

3rd.—Pulse 104 to 122; temp. 99.8° to 102.2°. Tongue dry and glazed. Restless at night, some vomiting in the morning, and a complaint of whatever she drinks making her feel sick. Right side of epigastrium occupied by a hard tumour, dull on percussion, tender on pressure, and presenting the characters of an enlarged left hepatic lobe. The tumour encroached slightly on the umbilical region. She vomited a good deal during the day, at times bringing up a small quantity of florid blood mingled with mucus. Pain (occasional) of a spasmodic twitching kind in course of ascending colon.

4th.—Pulse 108; temp. 98.2° to 101°. Pain and tenderness in right iliac region, but no fulness nor hardness to be felt here. Next day the temperature had assumed a lower level, the vomiting and retching had ceased, and the pain and tenderness were much better. The following day (December 6) the improvement appeared to be maintained, with the exception that there was a slight rise in pulse rate, the temperature not exceeding 100°.

7th.—Pulse 116; temp. 98.4° to 101.4°. *Pain in ankles*, but no swelling could be detected. An occasional dry râle heard over both bases, fair respiration on right side, except over a narrow strip at the very base, where it is absent. Bowels continue loose, but she does not pass more than two motions in the twenty-four hours. Some retching and inclination to vomit during the afternoon and evening. The next day the temperature ranged from 100° to 101°, and there was a slight fur on the tongue.

9th.—Pulse 128; temp. 103.2° at 7 a.m. (the highest point reached up to this), falling to 100° at 3 p.m. Cough troublesome, and occasionally inducing retching; thirst increased. The quinine mixture was stopped, as it appeared to increase the tendency to vomit, and a grain of calomel and three grains of Dover's powder prescribed every four hours.

10th.—Pulse 134; temp. 99.4° to 102°. Slept very well, but vomited a small quantity of yellow fluid during the night; shooting pain across right side, which is relieved by lying on that side. Brandy ℥ij., and beef jelly.

11th.—Pulse 128; temp. 100° to 101.4°.

12th.—Pulse 124; temp. 101° to 102.4°. Aching pain in right side, perspiring a good deal, especially about the head; slight dulness, marked respiration, and a minute râle at end of inspiration over lower half of right lung posteriorly.

13th.—Pulse 120; temp. 100.2° to 101.8°. Troublesome retching after almost everything she takes, dulness much

increased in intensity, and respiration very feeble over lower part of right lung behind. All medicinal treatment stopped.

14th.—Pulse 122; temp. 100° to 102.6°; resp. 24. Very restless this morning, and during the night very thirsty; perspiration not so great, feeble respiratory murmur, crepitating râles, and increase of vocal vibration over infero-posterior region of right lung.

15th.—Pulse 136; temp. 101° to 102.2°. She was reported to have slept very little during the night, but had a considerable amount of sleep during the previous day. Perspired a good deal in the night, retching rather less troublesome. Tumour in right side of epigastrium has increased in size, and become more prominent, and indistinct fluctuation was detected. More air seemed to enter base of right lung.

16th.—Pulse 134; temp. ranged from 103° at 3 a.m. to 101° at 7 a.m., which were the maximum and minimum points reached during this day. Slept a little better, not perspiring so much: retching still troublesome. Tumour has extended more over into the left side of the epigastrium, and down towards the umbilicus; pain; fluctuation not increased, slight icteric tinge. Three grains of quinine every four hours in powder, and also seven and a half minims of liq. morphia alternately at the same intervals.

17th.—Pulse 140 to 164; temp. 102° during the forenoon, 104.4° at 3 p.m. (the highest point reached in the illness), 104.2° at 7 p.m., and 102.8° at 11 p.m. At 12 noon the patient was seized with a very severe rigor (which I witnessed), during it the bed shook violently, and the face became cadaveric looking. A profuse perspiration set in after the rigor. Slept well during the night: pain shoots across the epigastrium on coughing. Tumour increased in size, and becoming red at its most prominent part: a pulsation is communicated to it, but no murmur is audible.

18th.—Pulse 128; temp. 99.7° to 102°. Tongue dry and furrowed in centre; slept very well, coughing a little; retching not so troublesome; no further rigor. Tumour much more prominent, extends as low as the umbilicus, and *distinct fluctuation* is present. This being the state of affairs, with the assistance of Dr. Oldham, I aspirated the abscess, with the effect of drawing off 8 ounces of foetid faecal smelling greenish pus, a large quantity of very foul gas also escaped, which impregnated the ward with its odour. After aspiration the epigastric prominence subsided, but there was left behind a hard flat, indurated tumour, extending almost to a level with the umbilicus.

19th.—Pulse 120; temp. 100.2° to 101.5°. Slept well; vomited three or four times during the night, but not since 4 a.m.; perspiring freely; moderate amount of deafness (quinine). Some swelling and fluctuation again in epigastrium. Expresses herself as "free from pain." Fine crepitating râles; rhoncus and tubular respiration heard over base of right lung posteriorly. One motion after an aperient pill and enema.

21st.—No material change during last two days. Temp. 100° to 101°. Some vomiting and nausea continue. Free discharge of foetid pus from puncture; charcoal poultices to be applied. Stop the quinine.

28th.—During the last six or seven days pulse has varied between 124 and 134, and temp. between 99° and 101.8°. It reaching the former on the forenoons of 23rd and 27th, and the latter on the forenoon of 26th. Discharge continues profuse and foetid. Signs of consolidation of right base.

Jan 4th, 1885.—Pulse 124. For the last seven days the temperature frequently fell to the normal, and only on four occasions exceeded 100°, twice reaching 101°. Tongue becoming moist and clean. Discharge much less in amount, and rather thick. The hard indurated base (which extended almost to the umbilical level) has become much less extensive. Dulness, tubular respiration, various sized râles and increased vocal fremitus still persist at right base.

8th.—Pulse 128; temp. has scarcely exceeded the normal for last few days, except on the evening of this when it reached 100.2°. Sleeps very well. Appetite improving. Discharge much less.

13th.—Pulse 128; temp. has been keeping well in bounds since the last report, but in the evening it rose to 101.2°, falling, however, on the morning of the following day to 99°, which was followed in the evening by a rise to 102.6°.

15th.—Pulse 120; temp. 98° to 101.6°. Condition of right base much improved, respiration, &c., has become almost

normal. Discharge very scanty. The opening is now being dressed with iodoform. Appetite variable.

22nd.—Pulse 144. For the last four or five days the temp. has assumed deep curves, varying from 98° to 102.4° which it reached on the forenoon of this and preceding day. Slight rigors, nausea, increased quantity of discharge. Return of cough, and of the physical signs at base of right lung to a limited extent. Ordered quinine and digitalis.

23rd.—Pulse 120. Temp. reached the normal line, and on the following day became sub-normal.

From this date on the patient began to convalesce satisfactorily. The wound healed, the temperature and pulse fell, the lung cleared up, and she was discharged cured about the middle of February.

*Remarks.*—The case just narrated presented several features, when first seen, which bore a resemblance to some of those met with in enteric fever, and it can be readily understood that, at an earlier period these symptoms were much more likely to lead the clinical observer astray than when the patient came into hospital. The phenomena of local lesions were referable to the thoracic and abdominal cavities, and to the inferior extremities. Thus, in the chest we had at the outset signs of a very limited pleural effusion on the right side, which soon vanished to give place to evidence of a low form of inflammatory consolidation of the lowest portion of the right lung, the intensity of the physical signs of which fluctuated considerably from day to day, until convalescence set in. It was in the abdomen, however, that the most serious local inflammatory manifestations showed themselves, and at one time there was some ground for the belief that typhlitis, peri-typhlitis, was threatening, this speedily subsided, and the brunt of the mischief became centred in the epigastric region, where, as we have seen above, an abscess of considerable dimensions formed. Lastly, there was a transitory and trivial pain in the ankles and feet, which apparently bore some resemblance to rheumatism. With reference to the cause of those symptoms, septic infection will probably suggest itself to the minds of many, and, indeed, it may have been the *fons et origo mali*, but no definite history of exposure to infection of this nature could be obtained. Nor was there, on the other hand, any history of local injury in the epigastrium, or hepatic region. Without stating positively that the case was one of septic infection, I am somewhat inclined to the belief that such was the case. Or, again, the chest symptoms and the iliac (right) uneasiness may have been the radiation of inflammatory mischief from the epigastric abscess as a centre, just as we see the surroundings of an inflamed organ taking on a less intense form of irritative reaction in proportion as the organ is receded from, as, for example, in a case of abscess situated in one of the inferior triangles of the neck, where, from a direct apposition of tissue, the upper part of the pleura becomes inflamed, and even the lung itself may become so implicated as to give rise to the fear that phthisis is about to set in, but which, on the abscess being opened and drained, quickly subsides, leaving the pulmonary tissue healthy as before. Thus, in this case, it is not at all improbable that the thoracic symptoms may have been due to the inflammatory mischief radiating from the epigastrium through the diaphragm into the chest. And on this hypothesis also may the nausea and vomiting, and the occasional moderate diarrhoea be explained. The question as to the situation of the abscess is one that is involved in no inconsiderable amount of obscurity. This obscurity would doubtless have been a good deal illumined had there been made a free opening into the abscess, as by this means the sac would have been much more easily explored than was possible through the small opening—about the size of a cedar pencil—that formed after the aspirator puncture. But the great dread of further operative proceedings manifested by the patient, and her earnest entreaties prevented us from doing what we felt would have facilitated and hastened her recovery. There would seem to be three probable situations for the abscess, and any of them would be in accord to a certain extent with the physical signs, and constitutional symptoms of the case, viz., 1. The left lobe of the liver; 2. It was a circumscribed peritoneal abscess; 3. It was a sub-peritoneal abscess, that is, situated in the cellular tissue immediately beneath the peritoneum. In whichever of these localities it may have arisen there is one thing certain, and that is, that in the first instance it bore every resemblance to an enlarged left

hepatic lobe, and its progress would seem to agree with such a theory. We are inclined, however, to decide against hepatic abscess, first, from its rarity in this climate, secondly, from the absence of jaundice, and, lastly, from the absence of bile pigment in the pus. The undoubted faecal smell of the pus and gas that escaped certainly leads to the belief that the intestine was in close proximity to the sac, and either a circumscribed peritoneal abscess, or one located immediately beneath the peritoneum, would, I think, be sufficiently near to be influenced by the intestinal exhalations. Taking all the bearings of the case into consideration, I would be inclined to decide in favour of a sub-peritoneal collection of pus.

## Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND.  
SUB-SECTION OF ANATOMY AND PHYSIOLOGY.  
MEETING HELD THURSDAY, MAY 7TH.

The President, Dr. J. CUNNINGHAM, in the Chair.

### FROZEN SPECIMENS ILLUSTRATIVE OF THE PARTS CONCERNED IN COLO TOMY.

THE PRESIDENT exhibited two frozen sections to illustrate the anatomy of the parts concerned in the operation of colotomy—(1) a transverse section through the third lumbar vertebra, slicing off the lower part of both kidneys, but the right being lower than the left more of it was to be seen in the section than the kidney of the opposite side; and (2) a section through the umbilicus, passing through the fourth lumbar vertebra at a point clear of the kidney.

In these sections he demonstrated the position of the descending colon in relation to the quadratus lumborum muscle, and also showed the manner in which the peritoneum was disposed.

### COMPARATIVE ANATOMY OF THE CHIMPANZEE.

THE PRESIDENT also exhibited a mesial section of a young male chimpanzee, and called attention to some points in which its topographical anatomy differed from that of the adult human subject, and resembled that of the human child.

### FIVE CASES OF MUSCULAR AND VASCULAR ANOMALIES.

Dr. HEUSTON read a paper on Five Muscular and Five Vascular Anomalies which occurred in the Carmichael College Dissecting Room during the session 1884-5. The first three muscular ones were examples of anomalous origin of the biceps. No. 1 presenting the usual triple origin of the muscle; No. 2 the triple origin with an insertion into the flexor carpi radialis and pronator radii teres, in addition to its normal insertion; No. 3 an example of quadruple origin, the internal additional head arising between the insertion of coraco-brachialis and the origin of brachialis anticus, while the external (which was very well developed) arose from the insertion of the deltoid and adjacent portion of bone between the origins of the triceps and the brachialis anticus. No. 2 was noticed on account of the insertion being peculiar when taken in conjunction with the triple origin, while No. 3 was stated as having been before described only by Wood, the other authorities describing the quadruple muscle having noticed other origins than those described. No. 4 and No. 5 were examples occurring in the right and left lower extremities of a female subject of the flexor accessorius longus digitorum, which was brought forward. In left extremity the muscle arose from the tibia, while in the right extremity it arose from the fibula, thus presenting in the one subject examples of the different origins of the muscle, and also having no fourth tendon to the flexor brevis digitorum in either extremity. The vascular anomalies described were:—No. 1, an example of the middle meningeal artery, arising from the ophthalmic within the orbit, and passing through the sphenoidal fissure, to be distributed as usual, while the foramen spinosum was absent on the left side, and on the right side was very badly marked, transmitting a minute artery which united with the abnormal vessel. No. 2 and No. 3 were examples of aberrant arteries, taking origin from the axillary and uniting with, in the case of

No. 2, the radial artery, and in the case of No. 3 passing between the heads of the median artery, to unite with a normal radial recurrent artery. No. 4 was an example of a supra scapular artery arising from the axillary artery which, having passed through the brachial plexus and under the transverse ligament, was distributed normally. No. 5 was an ulnar artery, which, rising at the usual place of division of the brachial, passed superficial to the muscles of the forearm to be distributed normally in the hand. In the forearm it gave off no important branch, while the ulnar recurrences, radial recurrent, comes nervi mediana, and inter-osseous arose from a common trunk.

THE PRESIDENT asked whether nervous supply of the additional heads of the biceps had been discovered?

Dr. HEUSTON replied that to the four heads the nervous supply was from the musculo-cutaneous nerve, and that it was particularly examined in the quadruple muscle.

Dr. BROOKS asked if the muscle arising from the tibia was inserted into the long flexor tendons alone, or also into the accessorius. During the past session, in Trinity College dissecting-room, he had noticed a similar case in which the muscle was attached entirely to the flexor tendons, passing partly into the accessorius, but chiefly into the band connected with the longus pollicis. He was enabled to trace the tendon out into three divisions. Unlike Dr. Heuston's case, the fourth tendon of the flexor brevis digitorum was not absent, but was normal.

Dr. HEUSTON, in reply, said the muscle was inserted into the long flexor tendons and accessorius, chiefly into the latter; its deeper portion only passing to the tendons. The point, however, which he considered of interest was not the exact attachment, but the fact of finding the different origins for the muscle in the one subject, and also that the fourth tendon of the flexor brevis was absent.

Dr. BROOKS communicated a second case of

### ANOMALOUS CORONARY ARTERY OF THE HEART.

This anomaly occurred in a subject in the dissecting-room of Trinity College, towards the close of the winter session 1884-85. A large branch arose from the right coronary artery, about one-third of an inch from its origin, and passed behind the root of the aorta and pulmonary artery; here it gave off three branches, which ran upwards on the trachea; it then divided into branches, which anastomosed in a complex manner with an abnormal branch, which arose from the right anterior sinus of Valsalva of the pulmonary artery. From the anastomosis so formed, two branches ascended in a tortuous manner in front of the bifurcation of the pulmonary artery and the transverse portion of the arch of aorta and united into one trunk, which joined an abnormal branch arising from the left subclavian artery near the origin of the vertebral. The three branches mentioned above as ascending on the trachea, after insinuating very freely, gave off a branch to the right bronchus, and then joined a branch arising from the posterior aspect of the arch of aorta, close to the termination of the transverse portion.

Dr. PURSER said that it was difficult to say how the blood flowed in this complicated arterial arrangement. One thing was clear—viz., that in a case of direct communication between pulmonary artery and aorta, the current must be from the latter into the former. Water would as soon pass up a hill as the current of blood in such a case could pass from pulmonary artery into the aorta, or, in other words, contrary to pressure.

Dr. HEUSTON said he had been much interested in a former case of anomalous vessel brought forward by Dr. Brooks, because he did not think it possible for arterial blood to pass as was described in both of those cases, considering the great difference of blood pressure on the right and left sides of the heart. In his opinion the vessel was a vein which, by the method of injection from the femoral artery, bursting, as it frequently did, the septum ventriculorum, allowed the injection into the right side of the heart, which then passed from the pulmonary artery into the vessel. Since the last meeting he had examined five hearts, and in three of those was able to demonstrate a vessel falling into either the right or left pulmonary sinus of Valsalva, and he was strongly inclined to think that such a vein was usually present; but the number of cases he had as yet examined did not warrant him in giving a positive opinion. In the present case, he considered the vessel to be a vein conveying the blood back from the junction of the normal and abnormal coronary vessels into the pulmonary artery.

## APPARATUS FOR ILLUSTRATING PULSE WAVES.

Dr. PURSER exhibited an apparatus for recording the movement of a wave along a tube, being an improvement devised by himself upon the apparatus of which Prof. Marey published an account in 1875.

## INTERESTING ANOMALIES RELATING TO THE (1) THORACIC DUCT AND (2) THE NERVE SUPPLY OF THE SEBRATUS MAGNUS AND LEVATOR ANGULI SCAPULÆ.

The PRESIDENT gave details of two interesting anomalies which had been obtained in the dissecting room of Trinity College.

Dr. PURSER drew attention to the mode of development of the spinal nerves, which would explain some of the cases connected with anomalies of this class.

Dr. HENRY KENNEDY called attention to recorded cases, where, as a general rule, the mischief occurred in the right side of the brain, and the left side of the body was the part that suffered, and *vice versa*. The point brought under notice was very important.

Dr. HEUSTON, referring to the relation of the phrenic nerve, stated that during the session he had noticed in the subject on which he was lecturing a well-marked example of Burns' nerve. On both sides, in tracing the nerve upwards, he found that the phrenic arose from both the fourth and fifth cervical nerves.

The PRESIDENT was glad his communication had elicited such an able discussion on the development of the nerves. The same point was passing through his mind as that adverted to by Dr. Purser as to the condition found in the decussation of the pyramids. With regard to what Dr. Heuston stated, he had never had the least doubt that the phrenic received fibres from the fifth.

Dr. HEUSTON remarked that what he was referring to was not communication between the fourth and fifth, but Burns' communication between the nerve to the subclavius and the phrenic nerve.

The Sub-Section then adjourned.

## THE EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Dr. ANDREW SMART, F.R.C.P.E., in the Chair.

At the Thirteenth Meeting of the present Session held on Wednesday, 15th July, Dr. WILLIAM RUSSELL read a note of a

## CASE IN WHICH A SPLASHING SOUND WAS HEARD SYNCHRONOUS WITH THE CARDIAC ACTION.

This unusual auscultatory phenomenon occurred in a healthy young man, who could give no further history than that the sound had appeared and again disappeared for a good many months. It was so loud that it could be heard easily by persons in the same room with him. It was, however, far more distinctly heard when auscultation was practised in a localised area in the fourth interspace. The splash occurred both with the systole and the diastole. It could only be explained as produced by the movement of fluid in an air-containing cavity. Percussion over the same area gave a distinct cracked-pot sound, so that it was evidently an air-containing cavity with free opening. There was no other sign or symptom of disease, with the exception of slight friction heard once over the pericardium. Dr. Russell argued, therefore, that the sound could not be produced by air and fluid in the pericardium or by the existence of a vomica in a contiguous portion of lung. They must look, then, to the stomach and intestines. He did not think it could be caused merely by a dilated stomach in contact with the diaphragm. The exact limitation to a particular area went against this view. He was inclined to think that they had to do with a hernia either of a diverticulum of the stomach or of the intestine.

Dr. BRAMWELL thought that the facts of the case excluded the possibility of an explanation based on the presence of air and fluid free in the pericardial sac or in the pulmonary tissues. While agreeing that probably the sound originated in the stomach, he was not certain as to the validity of the herniation view. He had more than once observed similar cases, where it was not necessary to predicate the presence of hernia. The exact limitation of the area of loudest sound seemed in this case to lend strength to the hypothesis.

Drs. Smart, Blair Cunynghame, Allen, Jamieson, and James also took part in the discussion.

## Dr. ALEXANDER JAMES then read a communication on NUTRITION AND GROWTH IN CONNECTION WITH PULMONARY PHTHISIS.

In an elaborate paper, he brought together a large number of important facts, on which he built a working hypothesis, explanatory of the more frequent occurrence of pulmonary phthisis at certain ages.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York by Messrs. WILLMER & ROGERS; Philadelphia, by Dr. BRINTON post free in advance, 5½ dollars (£1 5s. 6d.) per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-Office Order.

## The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 22, 1885.

## UNCERTAIN MATERIE MEDICÆ.

Dr. DANFORD THOMAS, Coroner for Central Middlesex presided on Thursday last over an inquest touching the death of a child eight months old, which occurred after administration of a mixture consisting of extractum conii, five grains; potassii bromidum, five grains; and aqua chloroformi, one ounce. It appears that, in the absence of the regular medical attendant, the prescription was supplied by a brother practitioner, who appended the direction that one tablespoonful of the mixture should be administered as a dose; but the chemist by whom the medicine was dispensed urged the patient's friends to disregard this direction, and substitute for one tablespoonful one *teaspoonful*. This amount was accordingly given, and soon after the child became violently convulsed in the upper extremities only, the lower limbs being apparently paralysed; and with the

ultimate result that death took place. In his evidence the practitioner responsible for the prescription made three important statements, to the effect that, firstly, he had committed an error in prescribing the extract of conium instead of the succus; secondly, that he had unintentionally written "tablespoonful" for "teaspoonful"; and, thirdly, that he regarded conium as a most unsatisfactory drug to use, and considered that it ought to be expunged from the Pharmacopœia. In the face of this last declaration it is impossible for us to avoid the conclusion that, holding this opinion, he acted most unwisely in prescribing a remedy which did not command his confidence, and of the effects produced by which he was, by his own admission, in a state of uncertainty. We hold it to be the cardinal duty of every medical man to rigorously exclude from his own "materia medica" every article he is not prepared to impose the most implicit trust in, under the assurance that it will produce in the patient for whom he prescribes it a certain definite series of results, the sequence and extent of which are accurately foreseen by him as the outcome of the teaching and experience on which his claims to practise the profession of medicine can alone be legitimately placed. In this case the practitioner in question does not disguise that he was in fault, and being so he deserved the censure with which his conduct was visited by the coroner.

Respecting the cause of death in the case of the child mentioned above, we do not propose to speculate. It may or may not have been associated with the administration of the medicine. The adult Pharmacopœial dose of the extract of conium is given at two to six grains, and taking three grains as an average, the proper dose for an infant under one year may be given as  $\frac{1}{4}$  grain. The amount contained in each dose of the mixture prescribed by the medical man in question, was, however,  $\frac{1}{8}$  of a grain, and it is of course possible to assume that this quantity might deleteriously affect a child in whom there was already to be feared the existence of a "tendency to death," and especially since the signs of hemlock poisoning were present after the medicine had been swallowed. On the other hand, had the prescription included only *five minims* of *succus conii*, or but  $\frac{1}{8}$  of a minim per dose, the proper dose for a child eight months old being at least *three minims*, absolutely no effect could have been produced by it, and its incorporation with the other constituents of the mixture would have been meaningless. On whatever grounds, therefore, we consider the prescription, its composition alone is suggestive of indefinite reasoning so far as one, and that an important, element of it is concerned.

Apart, however, from legal and ethical considerations, the incident, unpleasant as it must be to the principals in it, affords an instructive lesson on the subject of unreliable remedies. Unfortunately our materia medica contains not a few drugs which deserve the terms applied to conium; and still more unfortunate is it that these drugs in many instances act in the most powerful manner when they do produce the effects expected of them. Sometimes they are little more than inert bodies when introduced into the human system

even in large relative amount; while at others a minimum dose will set up effects altogether inexplicable when they are compared with what has been obtained with the same quantities previously. Elaterium forms a notable example of this peculiarity, and hyoscyamus is a further instance. In all these cases uncertainty is the result of deficient knowledge, and the direction in which we must look for improvement is in the study of individualism, a subject that is practically at present a *terra incognita*, but the exploration of which is at length beginning to arouse the attention and enthusiasm of investigators.

It is of course but little to the purpose now to ascribe the different results produced in different bodies by drugs to the modifying influences of individual peculiarities of constitution and texture; but the rapid advances of science in recent years lend colour to the expectation that this field of research may by-and-by be cultivated with such success as to yield a perfect harvest of riches, tending in the direction of exacter knowledge of the relations subsisting between active principles and the physiological processes they are employed to modify, to arrest, or to stimulate. Hampered though the pursuit of such prolific studies is by existing legislative restrictions on experimental research, there is still some indication that in time the true bearing of scientific investigation on the improvement of medicine will be appreciated by the general public; and even so small a matter as the inquest referred to above will help to this desired end by assisting, though ever so slightly, to show wherein the art of healing is weak, and by demonstrating the methods that must be followed, to the end that perfect enlightenment may be given to the physician.

#### CANCER CURES.

"HOPE deferred maketh the heart sick." Truly the hearts of medical men may feel faint and may be sickened, by the repeated failures to discover some plan of successfully dealing with that, *opprobrium medicorum*, cancer. Now and again, the minds of the profession are excited by the rumoured discovery of some new remedy. A rush is made to put it to the test, in the hope that the benefits claimed for it may be established, and, that at last, it may be within our power to hold out some hope to our suffering patients. Hitherto, alas, our hopes have been disappointed. The success that has attended the first experiments, fails to be repeated in other hands, however carefully the further experiments have been conducted. Who can explain either the first successes or the subsequent failures? We do not, for one moment, wish to question the reports of such cases as Clay's of Birmingham, the nature of which should be beyond all doubt, owing to that gentleman's diagnostic skill; nor can we believe, that in recording the results of treatment, he would wilfully overstate any of the facts observed by him. The Chian turpentine, which in Clay's hands was said to have proved of such signal service, has not, to say the least of it, been equally successful in the hands of others; nor have we seen, during the past four years, a further record of successful cases from Dr. Clay's pen. There is now almost an absolute silence as to its use in

the treatment of cancer. We trust, that if such a record of success exists, as that we would fain see, it may not be withheld. By this, if its claims to be a specific, or something approaching the nature of a specific, could be established, we ought to have had such an accumulation of evidence in its favour, as to place the matter beyond all question or suspicion. Much the same may be said of condurango, and of gallum aperinum, from both of which much was hoped for, but, of which, both have failed to satisfy the expectations raised concerning them. This absence from both the British Pharmacopœia, and from Messrs. Martindale and Westcott's very inclusive extra pharmacopœia, gives very faint support to their pretensions to be regarded as useful or reliable remedies. They have now fallen into the hands of the homœopaths, who do not fear to assert, that, in their hands, they are curative of this dreaded disease; and, that by their means, and that of hydrastin, and others of their remedies, they have been successful, even in its advanced forms, without resort to the knife. Happy men!!! happy are they either, in their superior wisdom and skill, or in their blind ignorance; of wilful roguery in making such claims, we wish entirely to acquit them. The latest candidate for the position of "specific" is a South American plant called "Alveloz," samples of which were sent in the beginning of the year, by the United States Consul at Pernambuco, to the State Department, with the report that several cases of alleged cancer had been cured by its application. Unlike condurango, which is given internally, alveloz is a local remedy, its effect resembling that of jquirity. Its application induces a profuse suppuration when brought in contact with a granulating surface. It has been tested by Dr. Smith Townsend, of the Marine Hospital Bureau, of New York. The case upon which it was tried was one of lupus of the nose which had existed near the angle of the patient's eye for over forty years. This case had resisted all former treatment, but under the action of the alveloz, the ulcer was cured within a few days, and the patient was exhibited before the New York Medical Society. Dr. Townsend tried it in a case of epithelioma of the face, notes of which he has promised to publish at the proper time. If the results have proved the success of the treatment, we may soon hope to hear more about it. No man, or class of men, will be more rejoiced to hear of, and welcome, any remedy which gives a fair promise of affording relief than the members of our profession. To them it is always a trial to face those amongst their patients who are affected with this disease, a trial from which, could they possibly do so, they would gladly escape. No matter how serious a case may be, it can be faced with some degree of buoyancy, so long as there is reasonable hope of success in its treatment or the power of soothing the way to the end, and so robbing it of its horrors. In phthisis fortunately the general bent of the patient's mind is hopefulness as to his condition, and prospects of recovery; in cancer however, this is not the case, despondency seems to be the characteristic of this disease, just as hopefulness is that of phthisis. Before concluding these remarks we cannot help touching upon the claims of those who profess to be able to cure undoubted cancer, by, as they assert, searching out the cause, and so attack-

ing the local manifestations. We are not alluding to those quacks who constantly insert long advertisements of such supposed cures in the daily papers, but to men who hold some qualification, who disclaim any secret nostrum, or specific treatment, but who, at the same time, assert that they have succeeded in relieving or curing cases which have failed to find relief at the hands of the most eminent men in our profession. To these cases they seem to be at liberty to refer, and to our own certain knowledge, they are recommended by those whom they have relieved to their friends and acquaintances, as having cured them of some tumour or other, which has been pronounced as cancer. These men complain that the members of the profession are prejudiced against them. Of course there is no excuse to be made for the manner in which some of these men practise; at the same time, not having done anything openly in violation of professional ethics, we see no reason why they should not come forward, and give precise details of their methods of treatment, with an accurate and fully verified record of the results, verified by those who are able to vouch for the truth of what is claimed. We feel quite sure that the profession is not so prejudiced as to lightly turn a deaf ear to anything likely to prove of service in so fearful and baffling a disease; and that if successful, their rewards in every way would be commensurate to the service rendered. To anyone who believes he has the power of curing, or even staying cancer, we feel assured unlimited opportunities would be afforded by those who are in the position to do so, of putting his ideas to the test. All that would be demanded is, that everything should be conducted openly and above board, a faithful record of the results obtained being kept, and the patients themselves to be submitted, before, and after treatment, to the observation of faithful and capable judges of their condition. All honourable-minded men must hold in scorn the man, who for mere personal gain, holds out hopes of cure, where there is no possibility of their realisation, but we have no desire to include in such scorn, or to hold up to contempt, men who are honestly convinced that they have succeeded where others have failed, and who, apparently, can adduce evidence in support of their claims. Such men we invite to openly demonstrate their powers, in the assurance, that if they succeed, under the conditions we have named, a full measure of honour and pecuniary success will be their reward. He who discovers a cure, or any method of successful treatment for cancer, will be a benefactor to the human race second to none, and deserves the highest honours and rewards that can be showered upon him. Remembering past achievements in the discovery of fresh remedies, or new powers for old ones, we cannot feel altogether hopeless, that some drug may yet be discovered which will accomplish the fulfilment of our hopes; but its virtues must stand the fierce test of universal experiment, before its claims are admitted.

---

#### PENSIONS TO IRISH POOR-LAW OFFICERS FOR ABOLITION OF OFFICE.

WE recently laid before our readers the proposed amalgamation of the Westport and Newport Unions, and the consequent impending abolition of all offices in con-

nection with the latter Union. We pointed out that, under the existing law, all such officers hold their appointments for life, or until the Local Government Board "deems them unfit," and that no power exists to remove them from office, or to withhold their salaries, or to grant them any pension for loss of office. We, therefore, expressed the opinion that such officers would continue to hold office, and must be paid, notwithstanding the amalgamation of the Unions. The Government has introduced the Bill for the purpose of dealing with this anomaly.

#### POOR-LAW UNIONS' OFFICERS (IRELAND).

A Bill for enabling Allowances to be made to the Officers of Poor-law Unions in Ireland on abolition of office.

Be it enacted by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

1. This Act may be cited for all purposes as the Union Officers (Ireland) Act, 1885.

2. (a) The Board of Guardians of any Union in Ireland may grant to any person retiring or removed from the service of the Union by reason of the abolition of his office, to whom a superannuation allowance might be granted under the Act of the Session of the 28th and 29th years of the reign of Her present Majesty, cap. 26, or any Act amending same, such annual allowance by way of compensation for loss of office as they might have granted to that person if he were retiring from his office by reason of permanent infirmity of mind or body.

Such allowances shall be granted in the same manner and subject to the same conditions, and shall be payable out of the same funds, as if it were a superannuation allowance granted in accordance with the provisions of the said Acts.

(b) In the case of the abolition of an office arising from the dissolution or alteration of a Union, the Board of Guardians of the Union in which the officer is employed may grant such annual allowance, subject to such conditions as aforesaid, at any meeting held during the month previous to the dissolution or alteration taking effect, provided that not less than six clear days' notice of such meeting shall have been given to each member of the Board instead of the notice prescribed by the said Acts.

The provisions of Section 2 of the Act of the Session 12th and 13th years of the reign of Her present Majesty, cap. 104, shall apply to any allowance granted under this section.

3. In case any person enjoying any superannuation allowance under this Act is appointed to be a Union officer in any Union, every such allowance shall cease to be paid so long as he continues to hold such appointment, if the annual amount of the profits of the office to which he is appointed are equal to those of the office formerly held by him, and in case they are not equal to those of his former office, then no more of such superannuation allowance shall be paid him than with the salary of his new appointment shall be equal to that of his former office.

It will be noted that under this Bill the guardians will be entirely at liberty to refuse to the officer whose functions are extinguished any pension or compensation whatever, and it is hardly necessary for us, in the light of past experiences, to express our apprehension that the majority of the Irish guardians will so refuse, and that thus the medical officers will be sent adrift without a shilling of compensation. The guardians will themselves be deprived of their offices by the amalgamation, and

they will have no inducement to do justice to the abolished officers and every inducement to save the rates, and we therefore regard this Bill as an insidious means of getting rid of the officers without trouble or expense. We therefore trust that an immediate and active effort will be made to obtain such modification of the Bill as will protect the interests of officers, or, failing such modifications, to oppose its passing by every possible means.

It is a monstrous proposition that when it suits the State to consolidate institutions for the purpose of saving money it should effect that object at the expense of the officers of such institutions, sacrificing them without scruple to suit a public purpose.

We may observe, further, that the Bill does not make any provision for including in the assessment of the salaries upon which the amount of pension is to be calculated, the public health salaries, the lunacy fees, or any other of the emoluments which are not at present within the scope of the Superannuation Acts, the consequence of which arrangement is that even if the guardians consent to grant an abolition allowance, no credit will be given for the emoluments under these headings, and the pension will be proportionately less in consequence.

## Notes on Current Topics.

### Hampstead Heath.

A most important and influential deputation waited on the Metropolitan Board of Works on Friday last, with the view to urge the desirability of acquiring about 270 acres of land adjoining Hampstead Heath, and adding it to the area already devoted to the recreation of the public. The deputation included Professor W. H. Flower, F.R.S., Baroness Burdett Coutts, Mr. Shaw Lefevre, Marquis of Lorne, Mr. E. Bond, &c. Mr. Shaw Lefevre acted as interpreter of the wishes of the deputation, and urged the proposed increase in the area of the ground of the Heath, the importance of which as a popular resort is shown by its crowded state on Bank holidays and other occasions. Its present dimension is but 220 acres, or only one-fourth the size of Wimbledon Common but one-third the area of Barnes Common. The sites it is proposed to purchase include the height known as Parliament Hill, at present the property of Lord Mansfield, and which commands extensive views of great beauty. It is much to be hoped that the opportunity now occurring of enlarging the area of so valuable a health resort as Hampstead Heath, and securing it as an ever-open space for the people, may be successful. Of course the cost of doing so must be considerable, the land in question being almost within the four-mile radius of Charing Cross, and consequently of great value for building purposes. This, however, ought not to be held a sufficient obstacle to acquiring the property on behalf of the public; for money so spent is a sound investment, the return for which will be found to consist in diminished death-rates and improved bills of health; and this too among the classes for whom it is most desirable to legis-

late in the direction of hygiene and sanitary improvements.

### Science Fellowships in Australia.

A MOST munificent gift has been made to the University of Sydney by a member of the Senate, the Hon. William Macleay, who has undertaken to found and permanently endow four Fellowships of £400 per annum each, to be attached to the Faculty of Natural Science in the University. Successful candidates for the Fellowships are required to have graduated B.A. in the Sydney University, and to be actively engaged in the study of natural science by research; they are debarred from holding any other considerable appointment, and each Fellow will be subject to annual re-appointment, this being considered necessary in order to prevent any abuse arising in connection with the endowment.

### Kettlewell Home.

ON Monday, July 13th, H.R.H. the Prince of Wales formally opened a new Convalescent Home for St. Bartholomew's Hospital patients at Swanley, in Kent. The building has been erected at the cost of Mr. C. T. Kettlewell, and is named the Kettlewell Home in memory of his brother. The land was given by an anonymous donor. It comprises fifteen acres. The Home is capable of accommodating forty-five male and fifteen female patients, and cost fifteen thousand pounds.

### Consultation Amenities.

THE case of gangrene of the hand which Drs. Russell and Molony, of Cashel, publish in our columns this day raises a controversy as to the treatment of such conditions which justifies our printing the communication, and leaving the question of amputation or no amputation, under the circumstances, to the judgment of our readers. Even if no surgical interest attached to the case, we feel that we ought not to deny Drs. Russell and Molony the opportunity of vindicating their professional skill, and defending themselves—by a proper method and through a proper professional channel—against a personal attack made upon them in a method and by a medium of publication which strikes us as very much the reverse of proper or even decent. Whatever the merits of Dr. Laffan's line of treatment may have been, we feel it our duty to express the opinion that no course of conduct which he could have adopted would have been more indecent or a greater outrage on professional propriety than his circulating amongst the non-medical public in his district a handbill in which the characters of his professional brethren are assailed. We are the more astonished that Dr. Laffan should have condescended to such a proceeding because he himself has been wonted to pose as the censor of professional morals, being the author of one of the Carmichael essays and the public exponent of various professional reforms, and we can conceive no other explanation of his conduct in this matter than a loss of temper and a lack of discretion. Dr. Laffan's handbill does not disclose any offence against him except a difference of opinion as to the propriety of amputation for the case in question, but—if he had been violently and unjustly

attacked—there were other means which he might have adopted for his vindication without discrediting his profession by resorting to handbills.

### International Medical Congress.

THE success of the next International Medical Congress is being seriously jeopardised by the continuance of disagreements among the different sections of the profession in America. The preliminary arrangements committee recently met in Chicago, and after making sundry alterations in the constitution of the Congress, including omission of the sections on dental and oral surgery, nervous diseases, obstetrics, &c., and having appointed chairmen of sections, it adjourned till May, 1886. A week later those members of the Congress who reside in Philadelphia met together, and decided that the changes made in the preliminary organisation and rules for the Congress had necessitated a meeting of the Philadelphia contingent, who there and then resolved that, in view of the injury likely to result from these changes, both to the American profession and to the Congress, their duty laid upon them the necessity of declining to hold any office whatsoever "in connection with the said Congress as now proposed to be organised." The importance of this incident may be gathered from the fact that the list of names attached to the resolution in question includes many who had already been appointed chairmen of sections by the Chicago committee, and among others the following:—Drs. David W. Yandell, Weir Mitchell, Samuel W. Gross, Da Costa, Hayes Agnew, Roberts Bartholow, Duhring, W. Goodell, Minis Hayes, Joseph Leidy, W. Osler Alfred Stillé, H. C. Wood, &c. The position and reputation of the well-known gentlemen included in this list are a sufficient proof of the importance of the split which has thus unfortunately arisen; and since, should the arrangements for the meeting be continued under the existing strained circumstances, nothing but disaster can ensue, it becomes an immediate question whether steps should not be taken for selecting another place than America as the scene of the next International Congress.

### Government and the Patent Medicine Stamp.

THE hopes of those who looked forward to legislation by the present Parliament directed to amending the abuses connected with the Patent Medicine Stamp Act, are doomed to disappointment. On Monday week Mr. Warton questioned the Government as to their intention of proceeding with the Poisons Bill, and was answered by Sir H. Holland, financial secretary to the Treasury, to the effect that the Bill would not be proceeded with this session. The Government, however, have decided on taking immediate steps to minimise the evil which, as we formerly pointed out, arises from the existence of the official stamp on patent medicine packages. This is almost universally looked on by the public as an endorsement of the value of the nostrum it protects; and it has again and again been urged that grave mischief is often produced in consequence. Henceforth this will be no longer possible, since the stamp will be printed across with the words "This stamp does not

imply a Government guarantee." A slight caution is necessary to prevent the employment of print so small as to hinder the object to be gained. The words should be bold and unmistakable, and extend right across the label.

#### Diequalification of Voters by Medical Relief.

We observe with satisfaction that a stormy career is in store for the Medical Relief Bill. Mr. Pell, an influential member of the Conservative party, has given notice of the following challenge on the subject. He will, on the second reading, move "That in the relief of destitute paupers by any poor rate this House declines to draw a distinction in favour of enfranchising those who obtain it in the form of medical treatment and those who are compelled to accept it in the form of bread." The Medical Relief Bill, which was issued last week, applies to the United Kingdom, and extends the scope of the clause relating to Ireland. The principal clause provides that where a person has, in any part of the United Kingdom, received for himself or for any member of his family any medical or surgical assistance or any medicine at the expense of any poor rate, such person shall not, by reason thereof, be deprived of any right to be registered or to vote either as a Parliamentary voter or as a voter at any municipal election, or as a burgess, or as a voter at any election to an office under the provisions of any statute. But nothing in the act shall apply to the election of any guardian of the poor, or of any member of any parochial board in Scotland, or of any other body acting in the distribution of relief to the poor from the poor rate. There is a retrospective clause practically bringing the Act into effect from the present moment.

#### French Views of English Morality.

It is curious to note with what avidity the French press has seized upon the doubtful "revelations" which have lately startled even placid John Bull out of his accustomed placidity. They unanimously accord to them a credence which they have long denied to any authorised or unauthorised version of the Vulgate, and proceed at once to sum up matters in a style and language which, while not wanting in energy, are notably deficient in good taste and common honesty. Such conduct might well be passed over with contempt were the offenders only such journalists as Rochefort and his coadjutors, but even *La France* out-herods Herod in this line. This paper, it is true, is no longer what it once was, since M. de Girardin left its *bureaux de rédaction* for a better world; nevertheless, we cannot but admire the tact and delicacy which briefly describes the members of our legislative bodies as *immondes pourceaux*, *ignobles drôles*, and so on with a string of epithets carefully if not judiciously selected. In fact, the conclusion is inevitable, the more one studies latter day French literature and journalism, that the reputation for politeness and urbanity which the French nation has always arrogated to itself is a palpable falsehood. The chivalrous politeness which prompts our Frenchman to doff his obsequious hat and to curb his ever too pliant back before the ladies whom he meets, is insufficient to protect the lady from his cynical allusions or open slander when her back is turned, or to

make him a safe custodian of her virtue if left in his charge. The joy with which they gloat over the recent revolting and sensational "disclosures" is not that of the many over a sinner who repents, but is the retaliation for the "respectability" which the English nation has possibly on insufficient grounds considered to be almost its exclusive property in face of the organised vice of the French capital. Whether the *Pall Mall* "facts" (clothed as they were in needlessly disgusting language) be true or false, the result may in the end be possibly beneficial, but in the meantime it is well to recognise that vice is of no particular nationality. Idleness and luxury everywhere tend to the blossoming of this baleful fruit, and that indifferently in all ranks of society.

#### The General Medical Council.

THE projected Autumn Session of the Council will not be held, as there is no Parliamentary work. We are at least glad that this determination has been arrived at, as a saving will thus be effected of some hundreds of pounds which would otherwise be wasted on the usual contest of tongues without exercising the least influence for good or evil on anything.

#### The British Medical Association.

THE Town Council of Brighton have invited the Association to meet there in 1886. The Council has decided not to admit ladies to the Annual Dinner.

#### Irish Poor-law Superannuation.

THE Mountbellew Guardians (Co. Galway) have unanimously refused to grant any superannuation whatever to Dr. Kerans, the medical officer of the Ahascragh Dispensary District. Dr. Kerans is 85 years of age, and served the guardians without complaint for 48 years. The chairman of the guardians stated that, if the pension were granted, it could not probably be enjoyed by Dr. Kerans for more than a few years, that it would amount to only a  $\frac{1}{2}$ d. in the £1 of taxation, that as half this amount would fall on the landlords the charge on the ratepayers would be only  $\frac{1}{4}$ d. in the £1; that this assessment on a farmer whose place was valued at £10 would amount to  $2\frac{1}{4}$ d. per annum, or about the price of an ounce of tobacco. Nevertheless a deputation from the ratepayers attended to overawe the Board, and succeeded in frightening the guardians so that the proposal for a pension got no seconder. This case follows fitly upon the case of Dr. Walker, of Bonmahon, reported by us the week before last, in which certain members of the dispensary committee wheedled a poor feeble old man, who had served them for near half a century, into resigning, not only his dispensary, but his other appointments unconnected with the Poor-law, promising him the pension if he would do so, and the moment they had succeeded in depriving him of his offices they went to the guardians and by their voice and influence induced them to refuse the pension. These are the sort of guardians to whose kindness, generosity, and sense of justice the Poor-law medical officers of Ireland are invited to entrust their future. These are the persons to whom the Government by its new Bill gives the power to remove Poor-law officers without fault and upon abolition of

office and authorises them to grant or refuse pensions just as they please.

#### Presentation to Dr. MacCabe, of Dublin.

THE occasion of the promotion of Dr. F. X. MacCabe from the position of Local Government Inspector for the Dublin District to that of Medical Adviser to the Irish Prisons Board was on Saturday last availed of by the Poor-law officers—medical and non-medical—of the County Dublin to testify their appreciation of Dr. MacCabe's services as Inspector, and their congratulations on his transfer to a more lucrative and less arduous office. Mr. O'Brien, one of the members of the Board, was present, and the officers were represented by Sir Charles Cameron, President of the Royal College of Surgeons, Dr. Chapman, Hon. Sec. of the Irish Medical Association, Dr. Davys, County Coroner, Dr. Usher (Dundrum), Dr. Neary (Howth), Mr. Cope, Clerk of Rathdown Union, and Messrs. Atkinson and Phelan, of the North and South Dublin Union. Dr. Jacob was also present. The presentation consisted in a valuable salver and a beautifully engrossed address, and it was presented by Sir Charles Cameron on behalf of the officers. Dr. MacCabe returned an appropriate reply, in which he referred with gratification to the friendly feeling which had always existed during the official relation between himself and the Poor-law officers.

We avail ourselves of the occasion to confirm from our own knowledge the warm expressions of approval used by the deputation in describing Dr. MacCabe's devotion to duty, and his happy power of combining the *suaviter in modo* with the *fortiter in re*. He has, in every office with which he has been associated, succeeded, with admirable tact, in maintaining discipline and his own dignity without bearing with unreasonable severity upon those whose work he was charged to supervise. We congratulate him on this additional testimony of esteem.

#### Fees for Inspecting Labourers' Dwellings.

THE Vice-Chairman of the Kanturk Board of Guardians has given notice to rescind the resolution giving to medical officers about one shilling for each house inspected and reported on under the Labourers' Dwellings Act, and to propose at the meeting to be held next Thursday that the doctors get no remuneration whatever. This mode of proceeding is quite consistent with previous acts of the same Board. It may be well to remember that this is a Board which the Local Government Board obliged to increase the salaries of the medical officers from £90 a year to £110. Again, the Kanturk Board refused to give any salary to their sanitary officers until the Local Government Board stepped in and fixed the sum at £20 per annum. It appears that the Local Government Board will have to interfere again on behalf of the doctors. The Kanturk Board are most generous with all officers except the doctors.

If the medical officers have been duly summoned to make the inspections they can—without any difficulty at all—recover a similar sum to that which the Youghal Guardians had to pay to Dr. Rogers and his colleagues.

AN Indian Good Service Pension has been conferred on Brigade-Surgeon J. Macdowell, of the Indian Medical Department.

THE latest cholera telegram from Spain gives the number of victims attacked last week at 11,000, and 4,970 deaths. The average number of fresh cases during the past three weeks has been 1,500 daily.

DR. PROTHEROE SMITH, the founder of the Hospital for Women, Soho, has, after 43 years of active work thereat, resigned the post of Senior Physician, and has been appointed Consulting Physician to the Hospital.

WE understand that the Guardians of Westport Union have taken every means to prevent the amalgamation of the Newport Union with theirs, and their representations to the Chief Secretary have been backed by a memorial from 1,500 of the ratepayers.

THE Mayor of Belfast, who has just received a baronetcy, now Sir Edward Harland, J.P., is a son of the late Dr. Wm. Harland, of Scarborough, thrice Mayor of that town, and nephew of Dr. Peirson, also of Scarborough, an occasional contributor to these columns.

### Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE REPRESENTATION OF THE UNIVERSITIES OF EDINBURGH AND ST. ANDREWS.—MR. ERICHSEN'S CANDIDATURE.—On Wednesday last Mr. Erichsen met the Universities' Liberal Association in Edinburgh, and delivered a brief address, in the course of which he described the arrangements which had been made in London to promote his candidature. At a meeting on the Saturday previous it had been moved by Dr. Robert Farquharson, M.P., and seconded by Dr. William S. Playfair, "That a London committee be formed, and that Sir Risdon Bennett, M.D., be chairman thereof." It had also been moved by Dr. Jas. G. Glover, and seconded by Dr. George Harley, "That the Committee consist of those now present, with power to add to their number." It had been moved by Dr. T. Lauder Brunton, "That the following gentlemen be a sub- or acting-committee, viz., Sir Jas. Risdon Bennett, Dr. George Harley, Dr. Farquharson, M.P., Dr. T. Lauder Brunton, and Mr. Meredith, surgeon; that the honorary secretaries be Dr. George Ogilvie, B.Sc., and Mr. Thomas Raleigh, barrister." Committees were also being formed in Manchester, Leeds, Liverpool, Newcastle, Bristol and Birmingham. Mr. Erichsen was received with great enthusiasm. At the close of the address, Mr. Aeneas J. S. Mackay, advocate (seconded by Prof. Chiene), moved, "That all those present form themselves into Mr. Erichsen's Edinburgh Committee (with power to add to their numbers), and undertake to do everything to secure his return to Parliament." It was further moved by Principal Tulloch, of St. Andrews, seconded by Professor Calderwood, of Edinburgh, that Professor Maclagan, M.D., of Edinburgh, and Prof. T. Spencer Baynes, of St. Andrews, be appointed joint chairmen of the General Committee.—On Thursday last, by invitation of Prof. Maclagan, M.D., Chairman of the Liberal Committee, a large and influential meeting assembled for the purpose of hearing an address

from Mr. Erichsen, F.R.S., who met with a very cordial reception. In the course of his address he explained how he came to stand before them. It was an honour that had been unsought, but one which, coming as it did, he had felt bound to accept. He felt deeply that a great responsibility was involved in following in the wake of such a distinguished and honoured man as their present representative. He wished them to know that he was a Liberal in politics, that he was so "in the fullest extent of the word, but not to its extreme extent." He was no party man, else he would not have sought to represent an academic constituency. He held strongly that an academic representative had far higher, nobler, and wider duties than the representative of an ordinary constituency. Passing to more special questions, he said that he stood before them as a medical man. He had long felt that the medical profession was inadequately and proportionately unfairly represented in Parliament. By this inadequate representation both the profession and the country suffered. Medical interests were injured and medical progress was hampered by *dilettante* and amateur legislation, while on social and hygienic questions involving medical skill and experience the public had not the benefit of the proper advice. He would only cite such questions as the general sanitary laws, those connected with quarantine, with the prevention and spread of infectious diseases, with compulsory vaccination, with the lunacy laws, with vivisection and the many knotty points in connection with the Contagious Diseases Acts. He then dealt at length with the subject of education. In regard to over-pressure, he believed that it existed, but not to so great an extent as had been alleged. He advocated greater attention to physical development. Turning to secondary schools and the Universities, he thought there was room for improvement. Certainly the Government would have to devise more liberal things for the Universities of Scotland. In conclusion, he referred to the subject of the disestablishment of the Scottish Church. He felt much inclined to follow the lead of Mr. Gladstone in this matter, and in the event of a responsible Liberal Government, guided by the will of the people of Scotland, taking action in the matter, he should feel it to be his duty to look with favour upon the action so taken by such a Government. At the close a unanimous vote of thanks was accorded to Mr. Erichsen for his address, on the motion of Prof. Laidlaw, Edinburgh, seconded by Prof. Knight, St. Andrews.

**CHAIR OF AGRICULTURE IN THE UNIVERSITY OF EDINBURGH.**—It seems doubtful whether the patrons of this chair can proceed to the appointment of a professor at present. The Treasury and the Highland and Agricultural Society, whose joint contributions towards the salary of the occupant amount to £300 annually, have both intimated that they intend to withhold this until full consideration has been given to a scheme for the further development of the teaching of agriculture.

**MIDDLE MEADOW WALK QUESTION.**—We read with pleasure that, by a majority of 23 to 11, the Edinburgh Town Council has rejected the proposal to open up the Middle Meadow Walk to carriage traffic. The Council is to be commended for this wise and courteous consideration of the interests of the Royal Infirmary and the University Medical Faculty, as well as for their far-seeing care of the burghers themselves.

**EDINBURGH UNIVERSITY.—MURCHISON MEMORIAL SCHOLARSHIP IN CLINICAL MEDICINE.**—The competition for this scholarship, open to competition annually among graduates of the Edinburgh and London Universities, has

just been held in Edinburgh. The first place has been gained by Joseph Griffiths, University of Edinburgh; *proxime accessit*, S. Plowman, St. Thomas's Hospital, London. The next examination will be held in London in 1886.

**UDDINGTON.—DEATH OF A CHILD FROM AN OVERDOSE OF LAUDANUM.**—A baby five weeks old died at Uddington on Tuesday, the 14th inst., from the effects, in the opinion of Dr. Crawford, of an overdose of laudanum, which the father, a stonemason, administered the day previously to relieve the child while suffering from "cramp" in the stomach. He is alleged to have given it four drops of the drug. This again shows the extreme danger of administering opiates to children. We recently heard a medical man state that he knew of a case of a child in which *three grains of muriate of morphia* (!) produced no bad results. We cannot believe that what was assumed to have been morphia was anything of the kind.

#### THE FORTHCOMING MEETING OF THE BRITISH MEDICAL ASSOCIATION AT CARDIFF.

It is thirty-two years since the British Medical Association met in South Wales. Cardiff in those days was but a small place, its population in 1851 being under 19,000; whilst, in this present year of grace, it is estimated as upwards of 100,000! Cardiff owes its present important position as one of the chief export towns in the Kingdom, in the first instance, to the enterprise of the late Lord Bute, and the energy of his advisers and trustees. For the amount of shipping cleared, it ranks as the third port in the United Kingdom. Its docks rank amongst the finest to be seen anywhere; and when the new dock, now in process of construction, and which will accommodate some of the largest steamers afloat, is completed, there will be an area of many acres covered by docks. The Penarth Dock, a short distance off, is also connected with the Port of Cardiff. The new Barry Dock, seven miles away, now being constructed, will occupy an area of forty acres.

In the centre of the town is Cardiff Castle, one of the residences of the Marquess of Bute. This Castle is being nobly restored by its owner; it and the Castle grounds will be thrown open to members of the Association. A short distance away is the ancient city of Llandaff, which, with its beautifully restored cathedral, presents many sources of interest and attraction to lovers of olden times.

At the annual gathering, which takes place next week, the post of President will be occupied by Dr. Edwards, senior physician to the Glamorgan Infirmary. There will be three addresses: one in Therapeutics, by Dr. Roberts, of Owens College; one in Surgery, by Mr. Marshall, lately Professor of Surgery in University College, London; and one in Public Medicine, by Mr. Dyke, Medical Officer of Health for Merthyr Tydvil.

The Section of Medicine will be presided over by Dr. Samuel Wilks. In this Section, there will be discussions on the Clinical Aspect of Glycosuria; and on the Treatment of Acute Rheumatism. That of Surgery will be presided over by Professor Bennett, President of the Royal College of Surgeons in Ireland. In this section there will be discussions (1) on the subject of Operative Interference in Intestinal Obstruction; and (2) on Bladder Tumours. In the Obstetric Medicine section, Dr. Gervis, of London, will be President. The subjects for special discussion are (1) the Third Stage of Labour; and (2) constitutional and topical treatment in certain forms of Uterine Diseases, introduced by Dr. Playfair.

The section of Public Medicine will be presided over by Mr. Davies, and the subjects proposed for discussion are four, namely, (1) Cholera; (2) the Dry Earth System; (3) Summer Diarrhoea in Children; (4) Legal Impediments to sanitary work and aims.

In the section of Psychology, Dr. Yellowless, of Glasgow, will preside. The subjects selected for discussion are: Treatment of Maniacal Excitement; Lunacy Legislation; Marriages of Consanguinity in relation to unsoundness of mind; Suicidal Insanity.

In the section of Ophthalmology and Otolaryngology, the post of President will be occupied by Mr. Henry Power, of London.

Pharmacology and Therapeutics will be presided over by Dr. T. Fraser, of Edinburgh. In this section the following subjects are proposed for special discussion: Anæsthesia, local and general; Diuretics; the Digitalis Group; the Duration and Action of Drugs, as shown by the sphygmograph, on Tensor Excitants and Depressants; Hypodermic Medication; Demonstrations.

The High Sheriff gives a garden-party on Wednesday afternoon, and the Windsor gardens at Penarth will be thrown open to members and their lady friends on Friday afternoon, when music and refreshments will be kindly provided by Lord Windsor. Besides the public dinner on Thursday, July 30th, to which it is proposed to admit ladies, there will be the soirée of the President and Reception Committee on the previous day, and the reception by the Mayor of Cardiff on the Friday, one or both of which entertainments will conclude with a ball. The Bute Docks, Tharsis Copper Works, Ely Paper Mills (where the paper is made from Esparto grass), Flour and Biscuit Mills, are some of the local industries which will be open to the inspection of members.

The Eighth Annual Meeting of the Irish Graduates' Association will be held in the Mayor's Court, Town Hall, at half past twelve, and not at five p.m. as in previous years. The associates will subsequently dine at 6.30, with Dr. Macnaughton Jones, the newly-elected president, in the chair. Full particulars will be found in our advertising columns.

There will be excursions to (1) Tintern Abbey and Raglan Castle; (2) Glastonbury Abbey and Wells Cathedral; (3) Trip by the Taff Vale Railway to Dowlais Iron Works, and thence to Caerphilly Castle, where refreshments will be provided by the kindness of Lord Bute; (4) Symonds Yat and Speech House; (5) Severn Tunnel, by invitation of Mr. T. A. Walker.

## Correspondence.

### THE QUALIFICATIONS OF HOSPITALS TO ISSUE CERTIFICATES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—You will oblige by giving a reply to the following queries:—

1. Can any of the licensing bodies refuse to accept the certificate of an hospital presented by a student seeking their diplomas "because that, during the session for which the certificate is dated the hospital authorities reduced the daily average of inmate patients to be not more than 49" (this number being far below the number the licensing bodies require by their curriculum the hospital to support).

2. Could the student make the hospital authorities recoup him for the various losses incurred (pecuniary, &c.) by the refusal of the certificate?

3. Which course would be the more "infra dig." for a Fellow of the licensing body to adopt? he being fully aware of the hospital rule: 1st. To inform the college and let it take whatever action its council might decide upon, or 2ndly, to silently allow the certificate of the hospital to pass muster, though, to his certain knowledge, there were not sufficient cases admitted either to satisfy the curriculum of his college, or give the student proper clinical instruction?

I am, &c.,

JOHN KING IRWIN.

July 11th, 1885.

[1. Those licensing bodies whose bye-laws or regulations specify a minimum number of beds as the qualification of an hospital to issue certificates, not only may, but must, refuse the certificates if it is brought officially to their knowledge

that the minimum qualifying number of beds are not maintained. We believe that in most licensing bodies such bye laws are in operation.

2. The hospital authorities have, by accepting payment of the fees, contracted with the student to give him the requisite certificate if his attendance be sufficient, and we believe that they will be liable for non-fulfilment of their contract if their certificates were refused recognition, and that, consequently, they would be open to a suit for damages unless they could show that the student, when he paid his money, knew that the certificate might not be accepted.

3. The course which a Fellow of the licensing body should adopt under the circumstances would depend very much upon whether it was his official duty to report the matter to the authorities. If he had no official relation to the licensing body, we do not think that his Fellowship would oblige him to interfere in the matter.—ED.]

### ON SEXUAL DEAFNESS AND DEFECTIVE SIGHT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR

SIR,—I was astonished to read in your issue for July 8th the statement of "An Obstetrician" that there is a growing opinion that under the guise of gynaecology much *demoralising* and unprofessional conduct is carried on, since I thought otherwise, and that obstetricians and gynaecologists had begun to take a foremost position in the profession. I am a specialist—a gynaecologist—but I don't "spay" nor practise os-splitting, though I have no small practice, and have had no small experience. The paragraph in your correspondent's letter to which I wish particularly to direct attention is the following:—"Everyone has heard of the case of an unfortunate lady who in one of our large Scotch cities slipped by accident into the house of a gynaecologist instead of that of his neighbour the aurist, and was there treated for deafness for six months *through a vaginal speculum*." Surely the writer, if an obstetrician and a gynaecologist, would not join in the laugh at the recital of such a story—a story true as regards the cure which might be effected, true as regards successful treatment in the way the writer despises, if not true as to the occurrence of the accident.

Since the days of Marshall Hall we have become accustomed to the study of reflex action and reflex irritability and irritation. The admirable papers by Dr. Routh "On the Constitutional Treatment of the Uterus and its Appendages," lately published in your pages, vividly portrayed some phases of this reflex action—and what obstetrician, what gynaecologist, is unfamiliar with the Proteans of these reflexes? Toothache in one or many teeth; sore-throat as a sexual reflex; eye affections of various kinds—I will not here stay to enumerate them—and defects of sight from utero-ovarian irritation. Every honest-minded and well-educated oculist and aurist must be familiar with such cases, almost as familiar, I should say, as his equally honest and well-educated brother in the profession—the obstetrician or gynaecologist. I could quote many cases occurring in my own practice corroborative of my statements. I will name one. Mrs. Ch— came to me with utero-ovarian irritation. She complained, likewise, that her sight had been decidedly growing more and more defective—that she was becoming more and more near-sighted. Without telling me she went to one of our famous oculists. He examined her eyes, asked under whose care she was, and for what. She told him, and his answer was, "You had better continue under his treatment; he can do more for you than I could." She continued the local utero-ovarian treatment, was quite cured, and the sight was restored also. The cases of deafness are equally well marked; and absurd as it evidently appears to be in the eyes of your correspondent, nevertheless it is a fact that "deafness" may best be "treated through the vaginal speculum," *i.e.*, by attending to the sexual organs, both through the vaginal speculum and without it in other ways. Here is the last case in point which has occurred in my practice:—Mrs. K. came to me complaining of being almost "stone deaf." I had to put my lips quite close to her ears and shout loudly before she could at all make out any of my words, so deaf was she. For years she had not entered a place of worship, and had had to withdraw from society, because of her infirmity. There was

also great general nervousness, such as we find existing in such sexual cases. I examined the ears, but found nothing wrong. I then asked her gynaecologic questions. Her answers led me at once to infer sexual deafness was what was present. I found the uterus tender, enlarged, engorged, and severe retroflexion existing. Positively I treated her deafness through, not the ear speculum, but the vaginal, by scarifying and punctating, &c. This done, I reduced the displacement, and placed a suitable pessary. Her deafness was soon better, and now she is able, as she and my class of pupils can testify, to hear me from the opposite end of a medium-sized room (consulting-room of our hospital) when I speak to her in my ordinary voice. So much for treating deafness through the vaginal speculum and per vaginam.

I exhibited this patient to my class of ladies the week before your correspondent's letter appeared, and she is to the front still to bear me out. I shall be happy to show her to any scientific inquirer. Other cases I could likewise adduce. Indeed, I have often in my lectures pointed out that what is throat deafness and nervous deafness is really in many instances but sexual deafness, that is, deafness proceeding altogether from disturbed conditions of the sexual system. Persistent and repeated sore-throats in young girls should at once cause the medical attendant to make inquiries as to the working of the sexual organs. Almost invariably he will find in them the cause of the throat affection, and often the concomitant "throat deafness" which in many instances may be present; and I have long been in the habit of teaching that these cases are only relieved permanently, or cured, by the girls getting married and becoming mothers; and "becoming mothers" I always add, for in the majority of cases marriage will not cure, though child-bearing will in most cases. It is true that advancing years, if they bring quiescence to the sexual organs, will, without marriage having been contracted, and without child-bearing having taken place, bring in their train a cessation to the throat troubles—the results of the sexual reflex irritation and disturbance. But often the deafness will be permanent, simply because the remedy has not been adopted in time, and what was once but a functional disarrangement has been allowed to pass into organic change, and what was before only a symptom has been permitted to become a veritable diseased state of the auditory apparatus, permanent and irremediable deafness being the result.

Yours, &c.,

G. DE G. GRIFFITH.

34 St. George's Square,  
London, S.W.

Literature.

TREATMENT OF LATERAL SPINAL CURVATURE. (a)

THE perusal of this work will prove of great advantage to those interested in the special subject of lateral spinal curvature. The author decrys in the strongest manner the application of many forms of mechanical treatment, save the rational treatment of lateral curvature known as the Roth treatment. At page 116 the author states: "The following are the leading points of my treatment, which has three parts, the preparatory, the curative, and the final. I claim for it priority and originality because it differs from any previous treatment. The word essay on the title-page of this little book will show that I did not intend to write an exhaustive treatise, but only some practical suggestions for those who wish to know something of the rational treatment of lateral curvature, and how to pursue this study." The author then goes on to state that the greatest attention is to be paid to the general state of health and strength. All suitable hygienic medicines and surgical means are to be used for the improvement and cure of any constitutional complaint or weakness. The causes which have produced or continue to keep up or to increase the curvature are as far as possible to be removed. Special attention is to be paid to any articles of dress interfering in the slightest degree with the functions of respiration, circulation, and digestion, or with the free movement of

(a) "An Essay on the Prevention and Rational Treatment of Lateral Spinal Curvature." With numerous Illustrations. By Matthias Roth, M.D. London: Baillière, Tindall, and Cox. 1885.

any part of the body. All positions preventing deep breathing, favouring and increasing the abnormal form of the neck, chest, shoulders, and spine, as well as stooping of the head, must be avoided. The final treatment consists in the instruction of the patient in such active movements as will contribute not only to retain the lately acquired improvement, but also enable him to make further progress in health, strength, and normal position. In conclusion, we confidently recommend the work, feeling sure that it will prove a valuable addition to the literature of this special subject.

THE ELEMENTS OF PHYSIOLOGICAL PHYSICS. (a)

THE work before us deals with that branch of science which comprises the application of physical and chemical principles, and laws giving an outline of the elementary facts, principles, and methods of physics and their application in physiology, the modern development of which has been largely due to the application of this science and physical law. The author states that in teaching this subject in the University of Glasgow, the want of a small text-book, containing the facts and principles of physics together with their physiological applications was felt. To meet this want the author states he was induced to give a series of weekly demonstrations to the students attending the classes during the winter months, and one of the results of that series is the text-book before us. The subject is divided by the author into eight parts containing forty-three chapters. The first part deals with electricity and magnetism and their application in physiology and medicine, then follow, in order: The graphic method, fluids at rest and in motion, the mechanics of the circulation, pneumatics, optics, sound, heat, and lastly dynamics. The book is carefully written and illustrated by over two hundred well executed woodcuts, while ample notice has been given to each subject, so much so, that we congratulate the publishers and the author on the creditable result of their labours.

New Inventions and Preparations.

NEW SOUND DEADENER.

DR. J. WARD COUSINS, Senior Surgeon to the Royal Portsmouth Hospital, sends us the following particulars of a little instrument devised by him, which consists of an elastic air cushion made in several sizes, as represented in

the engraving, to suit the varying capacity of different ears. We have not seen the instrument, and can therefore give no opinion from personal knowledge, but Dr. Cousins says that "as a sound deadener it powerfully modifies and reduces the intensity of sonorous vibrations, but it does not altogether suspend the sense of hearing. It can be instantly introduced into the aural orifice, and the deadening power can be regulated by the degree of firmness with which it is put in. It has proved an excellent ear protector for artisans and other persons exposed to the injurious effects of sound. It is also an excellent ear protector for swimmers and divers, and for all who suffer from aural disturbance after bathing. It forms a shield which effectually prevents the entrance of water into the ear, and, when used for this

(a) "The Elements of Physiological Physics." By J. McGregor-Robertson, M.A., M.B., O.M., Muirhead Demonstrator of Physiology and Assistant to the Professor of Physiology in the University of Glasgow. London: Cassell & Company, Limited. 1894.

purpose, it has proved invaluable to many patients labouring under aural delicacy and chronic disease. It has also been worn with great comfort by many suffering from abnormal aural sensibility associated with general nervous depression and debility; and by railway travellers and other persons unable to sleep in consequence of the disturbance and confusion produced by continual noise. It can be used as an ear protector during exposure to the blast of explosives, or severe cold or wind, and it forms an elegant substitute for the old-fashioned and unsightly plug of cotton-wool."

The Sound Deadener is very neatly made in flesh-coloured vulcanite by Messrs. Maw, Son, & Thompson, and I am much indebted to Mr. J. Banks of that firm for the care he has bestowed upon its manufacture.

#### IMPROVED HYPODERMIC POCKET CASE.

MESSRS BURROUGHS, WELLCOME, & Co. have introduced a most useful improvement in the shape of a compact and handy hypodermic pocket case, the value of which to physicians it would not be easy to over-estimate. The case

contains, in addition to the usual syringe and two needles, a dozen glass tubes, each holding a number of tableoids of drugs in doses ready for immediate employment, and needing only to be dissolved ere being used. The manufacturers have prepared a long list of agents in this form, any selection from which may be carried in the case, which also contains a small glass pestle and mortar for assisting the more complete and speedy solution of the tableoids. Its dimensions are no more than  $3\frac{1}{2}$  by  $2\frac{1}{2}$  inches, and its weight is almost inappreciable, so that it is easily carried in the waistcoat pocket, and for general use by practitioners there is nothing which in any way approaches it for convenience or utility.

#### SUMMER DRINKS.

THE advent of seasonable weather during the summer months is always heralded by unusual activity among manufacturers of beverages specially designed to satisfy thirst without producing the ill effects attending indulgence in alcoholic compounds. Many of the new drinks—a constant succession of which are offered to the public in this connection—have met with considerable favour. By some this has been maintained for a time only—"Zoedone," to wit—whilst others have increased their deservedly high reputation, and become standard beverages of the non-alcoholic class, highest among which still stands the ginger champagne made by Mr. Hay, of Hull, the success of which has induced that manufacturer to introduce other aerated drinks, some of which are now before us, under the style of lemon and orange champagne, orange quinine tonic, and tonic ale, all of which we find are made with that care and strict regard to purity of ingredients which has caused the name of Hay to stand so high in the list of manufacturers. These beverages are of the same sparkling character and purity of flavour noticeable in his previous ventures, whilst the usual medicinal dose of quinine has been embodied in the third on the list in such a way as to cover

the bitter principle to a certain extent, and it affords us much pleasure to offer a word of encouragement on their introduction.

"Lemon Squash" in bottles (each containing half a pint) is another novelty in summer drinks, and is produced by Messrs. Westmacott & Son, of Manchester. It possesses all the properties of a freshly-prepared "Squash," now so well known at public gatherings, and is a most successful attempt to bring the beverage within the reach of all at any time, and without the inconveniences attending its special preparation each time it is required.

#### Obituary.

##### JONATHAN ELMES, M.D., LIMERICK.

WE record to-day with regret the death of one of the best known of the public men of Limerick, Dr. Elmes, the favourite of the poor, the humane and indefatigable, who has just paid the debt which all mortals must discharge one day or other. In his tax cart with bells he went about every day on his visits, and the familiar figure was not missed until within the last few days, when it was announced that he had had an attack of paralysis. The doctor had to give up, and after a short illness he died at his residence, Thomas Street, deeply and sincerely regretted by every one, particularly by the poor, to whom he was constantly bountiful. The deceased was brother of the late Rev. Thomas Elmes, Rector of Killeedy, and of the late Rev. John Elmes, Rector of St. John's; and was distinguished apart from his professional services, for his love of books, and devotion to literature. He was a gentleman of peculiar manners and habits, but in all respects most courteous and considerate, and while he took no part in politics, his heart beat warmly for the interests of his country.

#### Medical News.

**King and Queen's College of Physicians.**—At the July examinations the following candidates, having passed the necessary examinations, received the Licences in Medicine and Midwifery of this College:—

**MEDICINE.**—Robert Hugh Arthur, Leonard Philip Banks, Louis Albert Frederick Bate, Alfred George Beale, Benjamin Blakemore, Edward Camall, William George Connor, Francis H. Daunt, Julius Barry Delany, John Empson, Henry James Flanagan, James Edward Grant, Michael St. Lawrence Harford, Thomas Walmsley Heywood, David Humphreys, Charles Granville Jackson, James P. James, Charles Trickey Jones, James G. Laing, John Murray Maclean, Timothy Aloysius Mulcahy, William James Neale, Robert Carson Nicholls, Robert Richards, William John Russell, Francis Howard Sinclair, Samuel Henry Steele, Alexander Stewart, David D. Tate, Richard Henry Verker, John Whyte, John Hall Woods.

**MIDWIFERY.**—Robert H. Arthur, Alfred George Beale, Benjamin Blakemore Edward Camall, William George Connor, Francis H. Daunt, Julius Barry Delaney, Charles Cochrane Dickson, Henry James Flanagan, Michael St. L. Harford, Thomas Walmsley Heywood, David Humphreys, James Gowans Laing, John Murray Maclean, Timothy Mulcahy, William James Neale, William J. Russell, Francis Howard Sinclair, Norman Smyth, Alexander Stewart, John Whyte, John Hall Woods.

The undermentioned were admitted Members after the necessary examinations:—

Charles Edward Fitzgerald. | William Cox Neville.

**An Important Sanitary Point.**—A case of considerable importance came before the Assize Court at Leicester a few days since in connection with the emanations of sulphuretted hydrogen evolved during the process of manufacturing sulphate of ammonia from gas liquor. The plaintiff was Mr. Donisthorpe, a large woollen manufacturer, whose works adjoin those of the defendant company. The action was brought to put a stop to the nuisance which resulted when the wind blew in a certain direction, and which caused, according to the plaintiff, a considerable amount of sickness among his workpeople. In view of the conflicting opinions of the local medical men, Dr. Gubb, of the French Hospital, London, was called upon to visit and report upon the presence and effects of the gas in the neighbourhood of the works. In the end, as the defendants claimed to have introduced such improvements into their machinery as to do away with the nuisance complained of, the judge ordered the matter to stand over for awhile, the works to be closed

should the emanations recur. The question as to the possibility of putting a stop to the discharge of poisonous gases into the air, even when the local authorities (who, as proprietors of the gas-works, are interested in disposing of the gas liquor) decline to interfere, was thus peremptorily settled, and the sooner the public are made aware of their rights in this respect the better will it be in the interest of public salubrity.

#### Society for Relief of Widows and Orphans of Medical Men.

—At the quarterly court of the Directors, which was held on Wednesday, July 8th, the President, Sir James Paget, in the chair, a sum of £1,437 was voted for distribution among sixty-six widows, ten orphans, and three orphans on the Copeland fund. The expenses of the quarter were £39 4s. The Treasurer informed the meeting that the grants already made this year exceeded by £308 those of 1884. Fresh applications for relief were received from two widows, and grants were made to them. No new members were elected; the deaths of three were reported, the resignation of another accepted, and four ceased to be members. The Directors fear that, owing to the increased demand on the funds, it may not be possible this year to give the usual present at Christmas, unless, by gifts and accession of new members, the sum necessary—between four and five hundred pounds—be made up.

#### Edinburgh University.—GRADUATION IN MEDICINE.—

The final examinations for graduation in Medicine have now finished. The general results have been most satisfactory. In addition to the names we have already published, the following gentlemen are gazetted as having passed at the latest sittings of the Examining Board, those marked with an asterisk having passed with distinction:—John W. Astles, Robert Newton Bell, Charles Norman Bensley, Charnchandra Bose, Alexander Brewster, Matthew Bruce, Robert Napier Buist, Robert Francis Burt, Stephen Frazer Clark, Arthur James Cross, Dina Nath Prithu Datta, Alexander Davidson, Joseph William Dawes, Robert Gordon, James Ashton Guthrie, Francis Kramer, M.A.; William Maxwell Little, Thomas Arthur Leishman, William George M'Phee, Charles J. Russell Maclean, Robert Sydney Marsden, D.Sc.; Robert Thornton Meadows, David Macbeth Moir, M.A.; John Kemp Murray, Alexander Paterson, Hugh Hampden Priddle, James Hogarth Pringle, Edward Thomas Pritchard, Selwyn Hall Puckle, M.A.; Alwyn Raimes, Charles Alan Renny, Francois Gideon Retief, John Theodore Richards, B.Sc.; John Brooke Ridley, George Matthew Robertson, Thomas Henry Robinson, \*Arthur MacLeod Ross, William Leighton Ross, Gerard Affleck Scott, William Edward Sawers Scott, Harold Scurfield, Charles F. D. Shaw, John Simpson, Ernest William Skinner, George Smith, Alexander Henry Smith, Walter Charles Spiller, George Laird Somerville, M.A.; James Stewart, Robert Stewart, M.A.; \*Harold Jalland Stiles, Robert Stirling, M.A.; David Sturrock, John Frederick Sturrock, John Sykes, William Symington, William Evans Thomas, John Tatham Thompson, Henry Thomas Tomlinson, Alfred Turner, \*Joseph Charles S. Vaughan, Simon Thomson Vine, James Robertson Wallace, George de Bourbonloun Watson, Alfred Bell Whitton, Sydney Taylor Williamson, George Edward Cartwright Wood. The second professional examination in medicine has now commenced, the written part being held on Friday and Saturday last. The orals are in progress.

**The Infectiousness of Small-pox.**—The *Times* newspaper publishes the following extraordinary piece of intelligence: "Mr. John Lotan, rural sanitary inspector of Oundle, Northamptonshire, has just died of small-pox contracted in pursuit of the duties of his office. It seems that a woman died in one of the parishes of Mr. Lotan's union, and it was rumoured that she had died of small-pox. In consequence, neither undertakers nor bearers could be obtained to bury the body, and the duty therefore devolved upon Mr. Lotan, Dr. Tomlinson, the medical officer of the union, and four assistants. A coffin was obtained, but as the undertakers would not approach the body to measure it, the coffin was made from guess measurement. This was after the body had been lying three days in the house. It was then found that the coffin was too small, and difficulty was experienced in making it serve its purpose. A few days afterwards symptoms of the disease were developed by all who assisted in the burial, except the doctor. As stated, the sanitary inspector, who was highly esteemed, died, and was buried within a few hours, the interment taking place at midnight. The four

assistants are still far from being out of danger. Special meetings of the sanitary authority have been held, and precautions have been taken to prevent the spread of the disease. The inhabitants of the infected places have been advised by the authorities to be revaccinated, and the advice has been followed by a large number."

**The Mortality of Foreign Cities.**—The annual death-rates per 1,000 in the principal foreign cities, according to the last weekly returns communicated to the Registrar-General, are as follow:—Calcutta 22, Bombay 27, Madras 31, Paris 19, Geneva 16, Brussels 20, Amsterdam 19, Rotterdam 14, The Hague 16, Copenhagen 19, Christiania 22, St. Petersburg 25, Berlin 30, Hamburg 24, Dresden 25, Breslau 34, Munich 27, Vienna 31, Prague 34, Buda-Pesth 34, Rome 23, Turin 21, Venice 22, Alexandria 37, New York 22, Brooklyn 19, Philadelphia 19, and Baltimore 18.

**Vital Statistics.**—The deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 18·3 per 1,000 of their population, and were in—Birkenhead 21, Birmingham 16, Blackburn 18, Bolton 13, Bradford 15, Brighton 15, Bristol 15, Cardiff 22, Derby 12, Dublin 22, Edinburgh 15, Glasgow 20, Halifax 13, Huddersfield 16, Hull 15, Leeds 15, Leicester 16, Liverpool 21, London 18, Manchester 25, Newcastle-on-Tyne 24, Norwich 21, Nottingham 15, Oldham 17, Plymouth 24, Portsmouth 16, Preston 18, Salford 21, Sheffield 18, Sunderland 21, Wolverhampton 16. The highest annual death-rates from diseases of the zymotic class in these towns were—From measles, 2·2 in Manchester, and 3·3 in Salford; from whooping-cough, 1·4 in Manchester and in Plymouth, and 3·2 in Blackburn; from "fever," 1·1 in Norwich, and 1·2 in Portsmouth; and from diarrhoea, 3·8 in Leicester. Small-pox caused 25 deaths in London and its outer ring of suburban districts, and but 3 throughout the other large towns.

## Notices to Correspondents.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**READING CASES.**—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

**LOCAL REPORTS AND NEWS.**—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

### WATERPROOF GARMENTS FOR DOCTORS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I would recommend your correspondent "Myosotis" to ask his tailor to procure the requisite quantity of a light tweed—light in texture and colour, and first having it made waterproof (but not airproof), to cut it into the form of a poucho (a loose cloak worn by the Indians in South America), which, when the wearer stands erect, should fall well over his feet and cover them. With the addition of a pair of waterproof leggings, the protection to the entire body from rain would be complete. The best processes for waterproofing are those by Potter and Cooley. By the first, let the cloth, wrong side uppermost, be covered with a solution of isinglass, alum, and soap, and when dry, let it be brushed against the grain, and then gone over with a brush wetted in clean water. Cooley's process consists in spreading the cloth on a smooth surface, wrong side up, and rubbing it over with pure beeswax (free from grease) until an even but thin coating is obtained. A hot iron should then be passed over the cloth, the latter being afterwards brushed whilst still warm. When in medical charge of Nynee Tal in the Himalayas, I found nothing so comprehensively protective against the drenching downpours in going my rounds on horseback during the rainy season as a large closely-woven blanket. These blankets are sold in the Hill bazaars, made into such a covering as that which I suggest. Mine was all in one piece without any opening except one for the head to pass through. I have always found macintoshes and the ordinary waterproof coats to be worse than useless. There is one objection of which by some might be considered to outweigh all the advantages of this kind of cloak—it rather makes one look like an undertaker!

Faithfully yours,

CHARLES E. FRANCIS (Surgeon-General).

Clapham Common, S.W., July 17, 1885.

MR. A. HODGES (Ryde).—We can make no promises in the direction mentioned.

DR. JORDAN.—The enclosures have been duly forwarded to the "Father of a Family," whose letter appeared in our last issue.

MR. STARTIN.—We hope to send you proof during the next few days. The delay is entirely due to increased pressure on our space on the part of an extended constituency.

C. E. F. (Clapham).—Happy to receive it at your leisure. Kindly keep it as short as possible, as we have still many papers awaiting space.

**SUPERANNUATION OF POOR-LAW OFFICERS.**  
To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—Will you please inform me (1) what are the necessary formalities to be gone through in the case of a dispensary medical officer of twenty years' standing who is about applying, or has actually applied, for a superannuation allowance, both with Dispensary Committee and guardians? (2) If it is necessary to have resigned before superannuation be granted? (3) If the majority of guardians grant it, is it then safe to resign? (4) Are the emoluments to be taken into account, or nett salary alone? (5) Off whom is the superannuation to be levied? Do the ratepayers and landed proprietors pay all? Is the entire amount to be levied on the dispensary district or union at large?

Yours faithfully,

SUPERANNUATION.

[1 and 2. Your resignation is to be addressed to the hon. sec. of your Dispensary Committee, but we strongly recommend you on no account to hand it in until the moment when the question of pension is being decided by the guardians. The regulation says that notice of consideration of the application must be given to the guardians a month before it is considered, and it has, heretofore, been usual to hand in the resignation at the time when the month's notice is given. This, however, it is not necessary to do, and it is most dangerous, because an interval of a month is afforded for agitation to those who are hostile; and, moreover, many guardians will vote for a pension for the simple purpose of getting rid of the officer who would certainly vote against it if he were already got rid of by resignation. We therefore advise you to write a letter to the hon. sec. stating your desire to resign if you get superannuation; to have that letter forwarded to the guardians, and a motion to grant the pension founded on it; to withhold the resignation until the hour of the guardians' meeting, and entrust it then to a friend to be handed in before the vote is taken if he thinks the vote is safe and not otherwise. The resignation must be officially declared before the motion is put from the chair. We have known numerous cases—e.g., those of Dr. Walker, of Bonmahon, and Dr. Alcock, of Kilmallock—in which the pension was considered perfectly safe, but it was lost because these precautions were omitted. 3. If a substantial majority votes for it, it is safe, but if a motion is given to rescind, it is probable that the Local Government Board will withhold its approval of the grant for a time in order to give the hostile guardians the chance of cheating the doctor. 4. Nothing is taken into calculation towards pension except the Poor-law salaries and vaccination and registration fees. 5. The pension is chargeable upon the same fund as the salaries.—ED.]

MR. ANSTIE.—Hardly suitable in its present form; but with a little alteration and addition it might easily be made so. The clinical details should be more elaborated.

W. M. C.—We cannot promise to accede to your request until we have had an opportunity of judging to what extent the subject has been correctly treated.

MR. DOWNING.—You cannot do other than offer an apology. You are most certainly in the wrong.

**COCAINE.**

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—I see many articles about Cocaine as a good remedy for *Hay fever* painted inside nostrils, 10-per cent. solution. I have found it as useful in many cases of pure spasmodic asthma and neuralgia, and can speak strongly on the subject, as it has done me personally much good.

I am, Sir, yours, &c.,

T. J. GELSTON, M.D., &c., &c.

14 George St., Limerick, July 11, 1886.

DRS. MILES AND WELDON.—See reply to Dr. Jordan. The letters have been forwarded.

MR. WEBSTER.—The result was doubtless due to the employment of impure glycerine. You cannot be too particular for experimental purposes. The only reliable preparation is Price's glycerine. The difficulty experienced in getting this article at the shops is on account of its higher price. If you repeat the experiment with this, we have not the slightest doubt as to a successful issue.

**VISITING IN POLICE CASES.**

A. D. says: I attended on a visiting ticket a prisoner in the police barracks one night recently and also in the morning. Can I obtain payment for doing so from the constabulary authorities? Is the ticket a legal one?

[If the ticket has been granted on behalf of a person who is not a fit recipient of medical relief you can recover the amount of fees from the issuer. But you must attend, and cannot claim any fee from the police. If no ticket had been issued it would be different.—ED.]

W. B. (Preston).—You should publish a statement of the facts, and then be guided by the opinions expressed by those who fairly consider them. We cannot advise you to follow the course of action you have suggested. It would be undignified to do so.

CAUSTIC.—Forward the prescription.

DR. BLAND.—The operation is not a favour one with surgeons in

the south, although there is a good deal to be said in its defence. The chief danger involved in its performance is that associated with opening into the knee-joint; and this is avoided by adopting the plan of subcutaneous division of the femur above the condyles. We are unable to give the reference you require.

**Vacancies.**

Birmingham, Parish of.—Three Temporary District Medical Officers. Salary, £400 each. Applications to the Clerk to the Guardians, not later than July 23.

Clonmel District Lunatic Asylum.—Assistant to Resident Medical Superintendent. Salary, £150, with apartments, &c. Election August 10. (See advt.)

Iale of Man General Hospital and Dispensary.—Resident House Surgeon. Salary, £100, with gas, coal, &c. Applications, with testimonials, to the Hon. Sec., not later than August 10.

Mason Science College, Birmingham.—Demonstrator in Physiological Department. Applications on or before August 20.

Netherfield Institution for Infectious Diseases, Liverpool.—Resident Medical Officer. Salary, £80 per annum, with board, &c. Applications, with testimonials, to the Secretary, on or before Aug. 1.

Owens College, Manchester.—Demonstratorship in Anatomy. Salary, £125 per annum. Applications to the Registrar, on or before July 23.

Ramsgate and St. Lawrence Royal Dispensary and Seaman's Infirmary.—Resident Medical Officer. Salary, £120 per year, with furnished apartments, &c. Applications, with testimonials, to the Secretary of the Dispensary, on or before August 1.

Royal College of Surgeons of England.—Examinership in Dental Surgery. Applications to the Secretary, before July 30. (See advt.)

Royal Infirmary, Ryde, Isle of Wight.—House Surgeon and Secretary. Salary, £50, with board, &c. Applications, with testimonials, to the House Surgeon and Secretary, not later than July 23.

St. Thomas's Hospital Medical School.—Demonstrator of Physiology and Practical Physiology. Applications to Mr. G. Rendle, at the Hospital.

Taunton Union, Churchstanton District.—Medical Officer. Salary, £55 per annum. Applications, with testimonials, to the Clerk, by August 1.

York County Hospital.—Resident House Surgeon. Salary, £100 a year, with board and lodging. Applications, with testimonials, to the Secretary, on or before July 25.

**Appointments.**

BARROW, F., M.R.C.S., L.S.A. Lond., Medical Officer for the Rothbury District of the Rothbury Union.

BARTON, G. H., M.R.C.S., L.R.C.P. Ed., Medical Officer for the Market Rasen District of the Caistor Union.

CHADWICK, G. F., L.R.C.P., L.R.C.S. Ed., Medical Officer for the Codford District of the Warminster Union.

CURTIS, D. T., M.D. Brux., M.R.C.S., L.S.A. Lond., Honorary Surgeon to the Bradford Infirmary.

GARDNER, T. F., M.R.C.S., L.R.C.P. Lond., Honorary Surgeon to the Bournemouth Cottage Hospital.

HENDERSON, C. M.D., C.M. Aber., L.R.C.P., L.R.C.S. Ed., Resident Surgeon to the Bathurst Hospital, New South Wales.

LUMLEY, B., M.R.C.S., Medical Officer of Health for the Northallerton Urban and Rural Sanitary District.

MARSHALL, W. J., M.D. Ed., Certifying Surgeon for the Greenock District under the Factories Act.

MAWBY, W. G., L.R.C.P., L.R.C.S. Ed., Medical Officer for the Blisworth District of the Towcester Union.

O'CALLAGHAN, R. T. A., L.R.C.S.I., L.A.H. Dub., Surgeon to the County Infirmary, Carlow.

O'SHAUGHNESSY, T. H., M.D., M.Ch.B.U.I., Assistant Resident Medical Superintendent to District Asylum, Ballinasloe.

POLLARD, R., M.B., M.R.C.S., House Surgeon to the Burton-on-Trent Infirmary.

ROYLS, J. F. S., M.B., C.M. Aber., Medical Officer for the Polesworth District of the Atherton Union.

**Births.**

DARLING.—July 10, at Lurgan, the wife of J. Singleton Darling, M.R., of a son.

LESLIE-JONES.—July 10, at Limefield House, Cheetham, Manchester, the wife of H. Leslie-Jones, M.D., F.R.C.S.L., of a daughter.

SCOTT.—July 17, at Shirley Lodge, Southampton, the wife of R. E. Scott (Surgeon-Major A.M.D.), of a son.

**Marriages.**

SADLER-HARVEY.—July 14, at St. John the Evangelist's, London, W.C., Michael Ernest, son of Michael Thomas Sadler, M.D., of Barnsley, Yorkshire, to Mary, daughter of Charles Harvey, of Barnsley.

SANDERS-BARTLETT.—July 18, at Holy Trinity, Cloudealey Square, London, Chas. Sanders, M.B. Lond., M.R.C.S., of Cheshunt, to Mary, eldest daughter of W. Bartlett, of Guildford.

WALSH-HOWLETT.—July 16, at the University Church, Dublin, Michael Walsh, L.R.C.S.I., L.R.Q.C.P.I., of New Ross, to Mary Aloysia, only daughter of William Howlett, New Ross.

**Deaths.**

ELMES.—July 17, at Limerick, Jonathan Elmes, M.D.

ENGLHEMART.—May 28, at New Calabar, Africa, drowned while crossing the river, Stephen P. Englehart, M.D. Ed., M.R.C.S., aged 54.

SMYTH.—July 10, at Suggden Road, Lavender Hill, Clapham, S.W., John Edward Smyth, M.D. F.R.C.S., aged 67.

WILKIN.—July 2, at Leinster Road, Co. Dublin, Thos. Hy. Wilkin, late Surgeon-Major 4th Battalion Durham Light Infantry, aged 83.

### ON SYPHILIS OF THE BRAIN. (a)

By JULIUS ALTHAUS, M.D., M.R.C.P. Lond.,  
Senior Physician to the Hospital for Epilepsy and Paralysis,  
Regent's Park, London.

A CLERK, *set*, 28, single, was admitted into the hospital under my care on November 28th, 1884, with the following history:—He comes from a healthy family, but had for years past committed excesses in drinking, smoking, and sexual indulgence; had had gonorrhoea half a dozen times, and syphilis about four years ago, *viz.*, a hard chancre followed by specific eruptions on the skin, which lasted for two or three months. After that he was apparently quite well until about twelve months ago, when he noticed that his left eyelid began to droop, and he had a difficulty in seeing with the left eye. At that time he was in Australia. Six months ago he returned to England, and after having been on board ship on his homeward voyage for about a fortnight, had one day, while sitting on deck, a stroke of paralysis which affected the right arm and leg. He lost neither his consciousness nor his language, but experienced a feeling of faintness, and then felt the paralysis gradually come on; there was no incontinence of the excreta, no affection of the face or tongue, no headache or sickness, and the paralysis had remained exactly the same ever since.

When I first examined the patient the most striking symptom appeared to be ptosis of the left eyelid and immobility of the corresponding eyeball. There was, in fact, *external as well as internal ophthalmoplegia*, owing to paralysis of the third, fourth and sixth nerves. This paralysis was complete in the superior and inferior recti, and the inferior oblique muscles; and incomplete in the levator palpebrae superioris, the internal and external recti, and the superior oblique. There was also paralysis of accommodation, and of the sphincter and dilator of the iris; the pupil was large, of ovoid shape,

(a) Read before the Medical Society of London.

insensitive to light, and only slightly influenced by eserine and atropine. Dr. Laidlaw Purves reported the ophthalmoscopic appearances of the fundus of the eye to be normal, the tension of the eye likewise normal, not bulging, not tender to pressure, vision 15-cc, colour vision fair. The right eye and eyelid appeared quite normal, and there was no disease in the other cranial nerves.

The patient's speech was slow, but he had never had any difficulty in articulation, expressed himself fairly well, and gave a tolerably clear account of the history of his illness. His intellect, however, seemed somewhat sluggish; there was a degree of hebetude; he appeared indifferent to his condition, did not complain at all, and showed great apathy altogether.

The right arm was in a state of paresis. The patient had considerable difficulty in moving it, yet succeeded in executing the various movements which I requested him to make, with the only exception of raising the wrist, which was impossible. He could not write, and had difficulty in feeding and dressing himself. The habitual position of the arm, hand, and fingers, was not that of late rigidity of the muscles, with which we are familiar in cases of ordinary permanent hemiplegia; yet on making passive movements a perceptible degree of resistance was encountered, showing some degree of rigidity. The patient squeezed the dynamometer to 20° with the right, and 70° with the left hand, showing loss of power of about 80° in the palsied arm, since in health the right hand is on the average about 80° stronger than the left, while here it was 50° weaker. The faradic and galvanic excitability of the suffering nerves and muscles was unusually brisk. There was no anaesthesia, nor any marked vasomotor or nutritive changes in the suffering extremity. A very striking symptom, however, was an enormous exaggeration of all the deep reflexes of the whole upper extremity. The slightest tap with the percussion hammer or the finger, not only on the points of predilection, such as the tendon of the biceps, the styloid process of the radius, &c., but on any other part of the arm and hand, caused the most extensive responses, the whole limb becoming violently agitated. Percussion of the left arm showed no such appearances.

The right leg was likewise in a state of paresis. The patient could walk slowly without assistance, but had great difficulty in lifting the foot from the ground, and was apt to scrape his boot against it; he walked on tiptoe; there was no absolute paralysis of muscles, but loss of power in all, and some rigidity in the hamstring muscles and those of the calf. Normal galvanic and faradic responses were easily obtained; there was no wasting and no anaesthesia. The most striking symptom in the leg, again, was the same enormous exaggeration of the deep reflexes which I have already mentioned as found in the arm. A strong ankle clonus could be easily excited, and the slightest percussion of any point of the lower extremity, more particularly the ligamentum patellae, the whole of the tibia, and the belly of the rectus femoris, threw the extremity into violent agitation.

The functions of the body were normal. The urine had a sp. gr. of 1022, and contained no excess of phosphates, no sugar, nor albumen. The patient was ordered iodide of potassium and inunction with oleate of mercury. This treatment was carried out with some interruptions, owing to affection of the gums and the mouth, which became somewhat rapidly established, until the patient left the hospital, two months after admission. There was, however, no amendment in the symptoms, except that the excessive violence of the deep reflexes had somewhat abated.

This case is interesting in several respects. In the first instance, the evolution of the symptoms of the patient's illness pointed so plainly to syphilitic brain-disease that the diagnosis could have been made without any inquiry about a previous specific sore or secondary symptoms. The man had had a stroke of hemiplegia at the age of 28, without any other systemic affection which could account for it; and it may be laid down as a general rule that if hemiplegia occurs in a patient between twenty and forty years of age who has no heart disease, diabetes, tabes, kidney disease, alcoholism, &c., and where there has been no preceding acute illness, such as pneumonia, &c., there is the strongest presumption that the affection is venereal. Another characteristic sign was that there had been no apoplexy at the time the stroke took place; for while the ordinary attack of hemiplegia from cerebral hæmorrhage, or from embolism of the Sylvian artery, is habitually accompanied by apoplexy, the syphilitic patient, when struck by hemiplegia, does not generally lose his consciousness nor pass the excreta under him, but habitually assists, fully conscious, at the invasion of the paralysis. Then, again, the palsy had been incomplete from the beginning, and had remained so throughout its further progress. This incomplete character of the paralysis is another peculiar feature of syphilitic hemiplegia; for while in ordinary hemiplegia there is complete loss of motor power, at least for the first few days or weeks of the illness, this is exceptional in the syphilitic variety, which is generally paresis rather than paralysis.

The present case is somewhat exceptional in not having been preceded by that peculiar form of headache which is so frequent a symptom of brain-syphilis; nor did it appear that any other premonitory signs, such as epileptiform convulsions, numbness and "pins and needles" in the limbs, vertigo, &c., had occurred. It remained uncertain whether the mental dulness and apathy which was now present had come on previous to or after the attack.

On the other hand, the complication of hemiplegia of one side of the body with ophthalmoplegia in the other side is most significant for syphilis. In the ordinary form of hemiplegia the only cranial nerves which are affected are the portio dura and the hypoglossus of the same side. In syphilitic hemiplegia, on the contrary, we frequently meet with palsies of the nerves of the eyes, more especially the third, but also the fourth and the sixth, either partial or complete. Such palsies, indeed, were long ago by Ricord called the signature of syphilis on the eye of the patient.

The last peculiar symptom which was present in this

case was the enormous increase of tendon reflexes in the palsied limbs, and which was quite out of proportion to the degree of the paralysis as well as of the muscular rigidity. Fournier, (a) in his able work on syphilis of the brain, has stated that there is not a single pathognomonic symptom whereby we can distinguish idiopathic from syphilitic hemiplegia, and that we must for our diagnosis rely upon the peculiar grouping and development of nerve-symptoms which occurs in constitutional syphilis; on the presence of equivalent signs in other organs, such as the skin, the testicles, the bones; as well as on the fact that syphilitic hemiplegia occurs not so much in the aged as in persons in the prime of life. Fournier does not say anything about the behaviour of the tendon reflexes in syphilitic hemiplegia, but goes on to state that the diagnosis can only be rendered certain by the results of specific treatment, as the latter may cure syphilitic hemiplegia, while mercury and iodide of potassium remain ineffectual in ordinary hemiplegia.

Now I have for some time past been of opinion that an excessive exaggeration of the deep reflexes in the palsied limbs in hemiplegia, points to a syphilitic origin of the affection. In 1882, I exhibited at the Clinical Society (b) a patient in whom this symptom was so highly characteristic that it attracted my special attention. The deep reflexes were so much increased in the paralysed leg that it shook fearfully on the least provocation, such as a sudden noise, opening the door, introducing the catheter, sneezing, coughing, &c. Percussion of the patellar ligament, of the tibia, and in fact of almost any point of the limb, induced violent so-called spinal epilepsy, which lasted for a considerable time, and was very greatly in excess of what is seen in ordinary hemiplegia. I have since then noticed this symptom in a number of other cases of syphilitic hemiplegia; and although I do not as yet feel justified in stating that it is absolutely distinctive of the syphilitic variety of hemiplegia, yet when present it raises *primâ facie* a strong presumption of it; and it may eventually be found that *excessive exaggeration of the deep reflexes*, more particularly when out of proportion to the degree of paralysis and muscular rigidity which may exist, is a *truly pathognomonic symptom of syphilitic hemiplegia*.

What was the nature and seat of the pathological lesion in the present case? The principal pathological change produced by syphilis consists of undue proliferation of cells; and this leads eventually either to the formation of gumma, or to sclerosis.

Gumma occurs chiefly at the base of the brain, where it tends to compress the nervous matter in its neighbourhood, as well as the blood vessels nourishing the same. Now the paralysis of the three cranial nerves which I have just mentioned point clearly to disease in the middle fossa of the base of the brain, and Nettleship (c) has lately recorded a case in which a spindle-celled sarcoma occupying the region of the right cavernous sinus, and also filling the sella turcica, has caused total external and internal ophthalmoplegia by compressing these nerves, and thus reducing their substance. There are, however, numerous other theories regarding the localisation of ophthalmoplegia to which I must briefly allude. Thus, Hutchinson, who was the first to describe internal ophthalmoplegia, located it in the lenticular or ciliary ganglion; while Hulke afterwards supposed it to be caused by disease of the intra-ocular ganglionic plexuses, which are in immediate relation with the ciliary muscle and the iris. There is, however, not the slightest physiological or pathological foundation for either of these theories; and Gowers and Allen Sturge have, with much better reason, sought the lesion more centrally, viz., in the posterior portion of the third ventricle and the floor of the aqueduct of Sylvius. This latter theory is supported by the physiological researches of Hansen

(a) La Syphilis du Cerveau. Paris, 1879. P. 461.

(b) Transactions of the Clinical Society of London. Vol. xv., p. 203.

(c) Transactions of the Ophthalmological Society of the United Kingdom, 1881. Vol. I., p. 166.

and Voelcker, who have discovered in the locality just named a motor centre for the external, as well as the internal, muscles of the eye, with minute differentiations for the innervation of the iris, the ciliary muscle, the rectus internus, and the other muscles of the eye. Thus far this discovery only holds good for the dog, but there is also some pathological evidence showing that this special motor area for the eye exists in man likewise. Kahler and Pick have reported two cases in which they found sclerosis of certain portions of this area, and to which during life had corresponded ophthalmoplegia; and Gowers has seen a case where external ophthalmoplegia was owing to degeneration of the nerve nuclei beneath the aqueduct of Sylvius, and in the floor of the fourth ventricle. I am, however, not inclined to think that this centre was affected in the present case, as it is a centre acting bi-laterally, and the ophthalmoplegia existed here only in the left eye. I am therefore of opinion that there was a gumma at the base of the brain, near the inner surface of the crus cerebri, and close to the anterior surface of the pons varolii, which by compression had caused wasting of the three nerves mentioned.

What was then the lesion causing the hemiplegia of the right side? Hemiplegia may be caused by disease at any point of the motor tract in the brain, between the central convolutions of the cortex and the medulla oblongata. The most frequent seat of the affection is in the basal ganglia and the white internal capsule; but I think that by assuming only a slight extension of the morbid process at the base of the brain, which I have just shown to have caused the ophthalmoplegia, the subsequent occurrence of hemiplegia in the present case can be easily accounted for. The crus cerebri, which is close to the paralysed cranial nerves, contains the motor tracts known as the crossed pyramidal strands in their course from the central convolutions to the spinal cord; and a further growth of the gummatous tumour which had already compressed the three nerves of the eye, would also compress the crus, and thereby cause softening of it, thus producing hemiplegia. This opinion is greatly strengthened by the fact that the paralysis in the present was, what is generally called, an *alternate* one; that is, the paralysis of the ocular muscles occurred on the opposite side of that of the extremities. Such alternate paralysis only occurs in disease of the crus, just as alternate paralysis of the portio dura and the extremities occurs only in disease of the pons varolii. The gumma must therefore in the present case be situated at the left side, that is, on the same side as the paralysis of the ocular muscles, and on the side opposite to the paralysis of the limbs.

The influence of treatment is sometimes exceedingly gratifying in syphilitic nervous affections, while in other instances is just the reverse. There is a general impression that the prognosis in specific lesions is better than in ordinary idiopathic disease, but this is only partially true, for many patients suffering from syphilitic cerebral affections, even if energetically treated on a specific plan, do not recover. This is explained by the circumstance that we have in cerebral syphilis to do not only with specific lesions, but also with secondary consequences of such, and these latter cannot be expected to yield to anti-syphilitic treatment. No doubt a gumma in the brain may be absorbed, and thickening of the membranes reduced, but where a gumma has already caused wasting of cranial nerves, and softening of cerebral tissue, that is, secondary and non-specific lesions, no amount of mercury and iodide of potassium can restore nerve-cells and fibres which have once perished. It is, therefore, only possible to cure such patients where the primary specific lesions have not as yet conduced to secondary ordinary lesions. The lesson which we have to learn from this should, therefore, be to subject patients, as soon as they show the slightest symptom of syphilitic brain disease, to an energetic specific treatment, so as to disperse the primary specific lesions, and to prevent as

far as possible the occurrence of secondary ordinary lesions, against which latter our remedies are known to be powerless. What occurs in syphilis of the brain thus affords a most striking illustration of the truth of the old Hippocratic maxim, 'ὁ θεὸς κείνος ὁ εὖς, the opportunity is fleeting! Let us, therefore, always endeavour to make use of it before it is too late.

## NOTES ON A CLASSIFICATION OF ERUPTIONS OF THE SKIN AFTER WILLAN. (a)

By JAMES STARTIN,

Honorary Surgeon and Lecturer to St. John's Hospital for Skin Diseases, London; a Vice-President and Honorary Secretary of the Willan Society.

GENTLEMEN,—Whilst our Society is still in its infancy, it occurred to me that a brief consideration of the nomenclature of skin diseases might not be without interest at the present time. The subject, I admit, is one which presents many difficulties and *has* done in the past, and teachers of dermatology in various countries have attempted to solve them, but, more or less, in vain, and often their efforts have ended in hopeless confusion. I know some teachers, professing to be practical men, look with contempt upon all nosological disquisitions, and deem such discussions idle, not conducive to the improvement of medical science. I am inclined to look upon this as a mistaken view of the subject, arising perhaps from indolence or want of precision in the use of language. It is not thus that science is extended. The advantages of a careful and definite nomenclature are—1st, An accurate investigation of phenomena; 2nd, Facilitation of the means of discrimination; for from a deficiency of terms we are prone to think or observe indistinctly. But, above all, a definite classification affords us with the means of imparting with precision, the information which we acquire. At the Dermatological Section held during the International Medical Congress in England, in 1881, so important was this subject considered that a committee of eminent dermatologists of England, France, Germany, and America was formed to prepare a classification for a future meeting. Nothing seems to have come of it at present. In introducing to your notice the present system of classification, I do not offer it as presenting much novelty, or of views peculiar to myself. It is formed upon the principles brought to light by Willan, and taught to me by my much-respected uncle, James Startin, some years ago. But, principally, it is founded upon clinical and pathological signs or manifestations occurring predominant in each eruption. We must all admit the service rendered to dermatology by Plenck in the early times, and Willan and Bateman and others in the French school, who rescued nomenclature out of chaos. This was carried out by a system of classification in eight groups, which were as follows:—

### WILLAN'S CLASSIFICATION.

- |                 |               |
|-----------------|---------------|
| 1. Bullæ.       | 5. Pustulæ.   |
| 2. Exanthemata. | 6. Squamæ.    |
| 3. Maculæ.      | 7. Tuberculæ. |
| 4. Papulæ.      | 8. Vesiculæ.  |

But as we find the study of dermatology advances, so we must increase our class. For instance, scabies and variola were classed under one head. Pustular lupus and acne under tubercular. In the present state of dermatological science, it must be admitted that all systems are more or less imperfect, but we are much indebted to the late Sir Erasmus Wilson, the late Dr. Tilbury Fox, and Professor Hebra—Kaposi and Duhring in the present, for much valuable work, and much clearer light has been thrown upon them.

The classification I now propose to put before you is as follows:—

- |  |  |
|--|--|
| 1. Cachectic Eruptions.                | 11. Sebaceous Eruptions.                       |
| 2. Chromatic (Colour), ditto.          | 12. Simulated, do.                             |
| 3. Erythematous, do.                   | 13. Squamous, do.                              |
| 4. Hæmorrhagic, do.                    | 14. Structural, do.                            |
| 5. Medicinal, do.                      | 15. Syphilitic, do.                            |

| 9. Papular Eruptions.                  | 20. Diseases of the Sweat<br>}       Glands.   |
| 10. Pustular, do.                      |  |

In preparing this classification, I have taken suggestions of Willan, Startin, Wilson, Kaposi, Duhring, and others, the main principles of which have already stood the test of some half century's work, clinical and microscopical.

**CLASS I.—Cachectic Eruptions.**—Showing some general constitutional cachexy or idiosyncrasy, congenital, super-vening, or acquired:—1. Cancerous affections of the skin, melanotic, carcinoma, epithelioma. 2. Cachectic ecthyma. 3. Elephantiasis græcorum; or true leprosy. 4. Fram-bœsia or yaws. 5. Scorbutic eruptions or sourry. 6. Strumous eruptions, scrofuloderma. 7. Lupus, L. Ery-thematous, and L. Vulgaris. 8. Rodent ulcer. 9. Sarcoma.

**CLASS II.—Chromatic or Pigmentary Eruptions.**—Showing changes of colour for the most part symptomatic of some constitutional vice or cachexy:—1. Achromia or spotted skin. 2. Albinismus or white skin. 3. Canities. 4. Cancer stain. 5. (C)loasma, discoloured skin. 6. Crimson stain. 7. Cyanoderma, blue skin. 8. Ephelis, sun-brown. 9. Lentigo, freckles. 10. Leucoderma, white skin. 11. Lepra alphoides. 12. Macula hepatica. 13. Melanoderma, black skin. 14. Morbus Adisonii. 15. Nitrate of silver stain. 16. Pigmentary moles. 17. Syphilis stain. 18. Zanthochoia icterus, yellow stain. 19. Pityriasis nigricans. 20. Nævus pigmentosus.

**CLASS III.—Erythematous.**—Showing heat, redness, tension, swelling, sometimes lymphoid inflammation, superficial, circumscribed, or diffused:—1. Acrodynia or epidemic erythema. 1. Anthrax or carbuncle. 3. Bucœmia tropica. 4. Erythema. 5. Erysipelas. 6. Furunculus or boil. 7. Hyperæmia folliculitis. 8. Inter-trigo. 9. Chilblain. 10. Frost bite. 11. Pallagra or Italian leprosy. IIIa. *Exanthemata*.—12. Urticariæ or nettle rash. 13. Burns and scalds. 14. Roseola (in-fectious). 15. Rubeola, measles (infectious). 16. Scar-latina (infectious). 17. Insect stings.

**CLASS IV.—Hæmorrhagic.**—Hæmorrhagic affections showing patches of hæmorrhage varying in size, under the epidermis, local or general:—1. Purpura, simplex, rheu-matica or peliosis rheumatica, hæmorrhagica. 2. Hæma-tidrosis or bloody sweat.

**CLASS V.—Medicinal Rashes.**—Showing eruptions by the administration of certain drugs:—1. Arsenic rash. 2. Arnica rash. 3. Bromide rash. 4. Belladonna rash. 5. Copaiba rash. 7. Croton oil rash. 8. Hyocyamus rash. 9. Iodine rash. 10. Iodide of potassium rash. 11. Iodoform rash. 12. Iodide of starch rash. 13. Quinine rash. 14. Sulphur rash. 15. Chrysophanic acid rash. 16. Tar rash and others. 17. Rashes produced by dyes.

**CLASS VI.—Neuralgic.**—Showing neuralgia with in-creased, vitiated, or diminished cutaneous sensibility, with or without eruptions or ulcerations:—1. Alopecia areata or circumscripta. 2. Hysterical anæsthesia and hyperæsthesia. 3. Neuralgic erythema. 4. Prurigo senilis. 5. Pruritus. 6. Herpes zoster. 7. Neurotic exoriation.

**CLASS VII.—New Growths. Neoplasmata.**—Showing growths upon the surface of the skin, in the blood vessels, connective tissue, lymphatics, and nerves:—I. Connective tissue: i. Moluscum fibrosum; ii. Keloid; iii. Zan-thelasma. II. Blood-vessels: i. Angioma; ii. Nævus vasculosus. III. Lymphatics: i. Lymphangioma; ii. Lym-phadenoma. IV. Nerves: Neuroma. V. Granulation tissue: Rhinoscleroma.

**CLASS VIII.—Parasitic.**—Showing animal and vegetable life, visible and microscopic, giving rise to various cutaneous manifestations, mostly contagious.

**Animal.**—I. *Dermatozoa*: Parasites which dwell in the substance of the skin. 1. Acne (see papular eruptions). 2. Guinea-worm disease. 3. Harvest insect rash. 4. Scabies. II. *Entozoa*: Parasites that live on the surface of the skin. 1. *Morbus pedicularis*: Pediculis capitis, or head louse, P. corporis, or body louse, P. pubis, or crab louse. 2. Pulex irritans, or flea. 3. Cimex lectuarius, or bug. 4. Pulex pipiens, or gnat. 5. *Æstrus*, or bot. 6. Pulex penetrans, or sand flea.

**Vegetable.**—1. Aphophyta, or thrush. 2. Alopecia, parasitica. 3. Phytiform disease (or ringworm) of scalp. Phytiform do. (or ringworm) of body. 4. Phyti-form disease of scalp, called favus. 5. Phytiform disease of beard, called sycosis. 6. Phytiform disease of body, called Pityriasis versicolor. 7. Tropical ringworm. 8. Phytiform disease of eyelids, called Tinea Tarsi. 9. *Mycosis*: ears, anus, vagina, and nipples. 10. *Mycoderma*, or fungus foot of India. 11. Onycho-phytosis, phytiform disease of the nails.

**CLASS IX.—Papular.**—Showing red points, or papules more or less mixed, disseminated or confluent. 1. Acne, Simplex, punctata. 2. Hyperæmia cutis, or cutis anserina. 3. Lichen and its varieties. 4. Pityriasis pilaris. 5. Strophulus.

**CLASS X.—Pustular.**—Showing pustules, blebs, or blisters containing matter or pus, sometimes bloody, with or without an inflamed cutaneous surface or base, isolated or confluent. 1. Ecthyma. 2. Impetigo. 3. Impetiginous eczema. 4. Rupia. 5. Sycosis. 6. Variola. 7. Varicella. 8. Vaccinia.

**CLASS XI.—Sebaceous.**—Showing an unctuous secretion from the sebaceous follicles, exuding, or expressed by pressure, adherent or non-adherent to the skin. Due to faulty secretion or excretion of sebaceous matter. 1. Acne sebacea: Comedones albidæ or seborrhœa. 2. Asteodes. 3. Chomasteodes. 4. Hordeolum, or sty. 5. Moluscum contagiosum, or acne moluscum. 6. Sebaceous tumours. 7. Zeroderma, Ichthiosis.

**CLASS XII.—Simulated.**—Instances in which various eruptions have been self inflicted by using some irritating substance on the skin; or by rubbing or scratching the skin. 1. Alopecia. 2. Discolourations. 3. Eczema. 4. Erythema. 5. Pemphigus. 6. Ulcerations.

**CLASS XIII.—Squamous.**—Showing scales, loose or attached to the skin, with or without an inflamed base, often in form more or less circinate, accompanied with irritation generally. 1. Eczema siccum. 2. Ichthiosis. 3. Pityriasis and its varieties. 3. Psoriasis or Lepra. 4. Dermatitis exfoliativa.

**CLASS XIV.—Structural.**—Showing changes, or new growths in the skin. 1. Cicatrices. 2. Corns or clavi. 3. Fibroma. 4. Keloid. 5. Morphœa. 6. Nævi. 7. Moles. 8. Scleroderma. 9. Verrucoe or warts—i. Vulgaris; ii. Seniles; iii. Acuminata. 10. Tylosis or cal-liosities. 11. Horns. 12. Nævus pilosus. 13. Elephan-tiasis arabum.

**CLASS XV.—Syphilitic.**—Showing eruptions due to a specific poison either hereditary or acquired. 1. Syphi-litic acne. 2. Syphilitic alopecia. 3. Syphilitic ecthyma. 4. Syphilitic herpes. 5. Syphilitic lichen. 6. Syphilitic macula. 7. Syphilitic onychia. 8. Syphilitic pem-phigus. 9. Syphilitic psoriasis, palmaris and plan-taris. 10. Syphilitic roseola. 11. Syphilitic squamous eruptions. 12. Syphilitic tubercula eruptions. 13. Syphi-litic ulceration and gummata. 14. Syphilitic vesicular eruptions.

**CLASS XVI.—Tubercular.**—Showing red, raised and inflamed tubercles and swellings, sometimes single, and sometimes confluent, occasionally suppurating or ulcera-ting. 1. Lupus cum hypertrophy (see cachectic erup-tions). 2. Moluscum (see new growths). 3. Sycosis indurata (see pustular eruptions). 4. Tubercular syphilis (see syphilitic eruptions). 5. Tubercular (cro-

fula (see cachectic eruptions). 6. Urticaria tuberosa (see erythematous eruptions).

CLASS XVII.—*Ulcerous*.—Showing a solution of continuity with or without sloughing and an inflamed base, often attended with varix on the lower extremities (see erythematous). 1. Anthrax ulcer. 2. Erythematous ulcer. 3. Ecthymatous ulcer. 4. Impetiginous ulcer. 5. Lupoid ulcer. 6. Parasitic ulcer. 7. Rodent ulcer. 8. Syphilitic ulcer. 9. Scrofulous ulcer. 10. Rupial ulcer (see cachectic eruptions). 11. Varicose ulcer. 12. Simple ulcer. 13. Fissures.

CLASS XVIII.—*Vesicular*.—Showing vesicles, blisters, blebs or bullæ, containing a sero-purulent or serous fluid, with lymphoid encrustation, and a phlegmonous base, sometimes causing excoriations. 1. Ampullæ. 2. Eczema. 3. Herpes. 4. Miliaria. 5. Pemphigus, vulgaris, foliacius, cheiro-phomox. 6. Sudamina. 7. Scalds. 8. Hydroa, and its varieties.

CLASS XIX.—*Diseases of the Hair and Nails*.—Showing certain conditions of the hair, and nails of an unhealthy state, baldness, roughness, ringed hair.

*Hair*.—1. Alopecia. 2. Ringworm, or phytosis. 3. Hirsuteæ. 4. Nævus pilosus. 5. Trichoeis nodosa. 6. Plica polonica. 7. Parasitic sycosis of beard (see Parasitic Eruptions). 8. Parasitic affection of eyelids (see Parasitic Eruptions). 9. Splitting of the hair and abnormalities.

*Nails*.—1. Onychia.

CLASS XX.—*Diseases of the Sweat Glands*.—Showing increased activity, and sometimes inflammation of the sweat glands, with or without pigment. I. *Quantity*.—1. Hyperidrosis. 2. Anidrosis. II. *Quality*.—Bromidrosis, Chromidrosis. III. *Retention*.—Drysidrosis, Sudamina.

This system of classification I therefore offer you for your consideration and criticism. I have followed as nearly as possible those prominent symptoms in each class and variety as we generally see them before us. It will be seen that I divide them into twenty classes, as few as I deemed necessary in so vast a subject, and these again into their varieties or subdivisions.

I have made separate classes of the syphilitic, parasitic, diseases of the hair, and diseases of the sweat glands, as I considered them severally of sufficient importance to do so.

The neuralgic class or tophic disturbance of nerve influence, is important, for as yet we do not know how many eruptions are due to nerve disturbances. I believe myself we are coming to a time when we shall include many more eruptions in this class than here stated, such for instance as erythema, urticaria, prurigo, some forms of eczema.

On the class of parasitic eruptions I have bestowed much care and study, and have enumerated all those known in this country. Why the term ringworm or tinea, is still adhered to in the new nomenclature I cannot conceive, both are misnomers, the vegetable parasitic growths are essentially phytiform in character. I have added a class also, simulated eruptions, as we sometimes have these cases brought under our notice, and it is important at once to recognise them, and so prevent deception. Medicinal rashes also claim our attention occasionally and should be known, as they are often liable to puzzle and trouble the practitioner in his diagnosis and treatment of eruptions.

Diseases of the hair are now claiming much of our attention as dermatologists, Trichorexis nodosa, and other newly noticed diseases of the hair. I have much studied of late the varieties and special characteristics of many nutritive diseases of the hair.

In concluding this short paper, I cannot close my remarks without referring to the habit dermatologists are falling into, in calling a compound eruption, viz., Lupus psoriasis, acniform lupus. I cannot help thinking that this will lead to much confusion. Why not name a disease that has the two prominent characteristics, Lupoid psoriasis; psoriasis-like lupus.

I have endeavoured to use English language in this classification as much as possible, but in the varieties I deem it best, to hold the long known and familiar names, mostly Latin, so that there may be no further confusion added to our already extensive glossary.

17 Sackville Street, W.

## HISTORY OF THE PROGRESS OF LARYNGOLOGY FROM THE EARLIEST TIMES TO THE PRESENT.

By GORDON HOLMES, M.D.,

Physician to the Municipal Throat and Ear Infirmary, London; Consulting Physician to the Sheffield Ear and Throat Hospital.

Il importe beaucoup de connaître l'histoire de la science à laquelle on s'attache.—Boerhaave.

### EPOCH I.—THE PRE-LARYNGOSCOPIC AGE.

(Continued from page 74.)

THIRD PERIOD.—*From the Death of Galen to the Death of Actuarius*.—About 200 A.D. to 1350 A.D.

THIS period might almost be passed over without any notice as far as the literal title of our subject is concerned, for, in a detailed account of laryngology, as well as of science generally, we should have to describe a movement of retrogression rather than of progress. During one or two hundred years medical science was maintained, if not positively advanced by the writings of Antyllus, but in the fifth and sixth centuries we discover no higher efforts than the compilations or collections of excerpts by Oribasius and Etius. Yet a century later on Paul of Ægina and Theophilus produced thoughtful and studied treatises, showing themselves at least to be well versed in the work of their most eminent predecessors. With these writers the flame of Grecian science expired, not to be relit after six hundred years by the unsupported efforts of John the Actuary at Constantinople.

Whilst, however, the most unproductive period reigned in Europe, the power and civilisation of the Arabians rose to the highest, and in this quarter science was vigorously supported and even extended from some of its old frontiers from the ninth to the twelfth centuries. Thus, the realm of Islam from the Tigris to the Ebro was illumined by the writings of Rhazes, surnamed the Magus, from his marvellous erudition, of Haly Abbas, of the prince physicians and philosophers, Avicenna and Avenzoar, of Averroes, of the observant surgeon Albucasis, and others. (1) Of medicine they were intelligent and erudite exponents, mingling a profound study of the Greek and Latin authorities with a rational empiricism of their own. After the immense strides made by Galen and his immediate predecessors in the anatomy, physiology, and pathology of the larynx, we may be prepared to find nothing worthy of record in these branches of laryngology during the present period. No extension of knowledge was, in fact, made, that can be registered under these headings, and we shall, therefore, only avoid recapitulation by omitting these sections altogether.

*Treatment*.—The same remark would also apply to treatment were it not that we have something to arrest our attention in the progress of opinion and practice as to laryngotomy. In the first or second century after Galen this operation, previously looked on as a mere vision, seems to have become an accomplished fact, and Antyllus, a skilful physician, who practised at Rome about that time, has left a circumstantial account of the method of performing it. The works of Antyllus have perished, but his opinion had so much weight with his successors that they have often quoted him verbatim at great length. These extracts, found mostly in Oribasius and Etius, relate chiefly to the use and abuse of the voice, and make it plain that Antyllus was, if we may employ the expression at so early a date, the most advanced laryngologist of his time. Paul of Ægina (about 650 A.D.) has preserved (2) his description of laryngotomy in a brief and after containing also his own views, and the passage

may be transcribed here in its entirety:—"The best surgeons have described this operation. Antyllus speaks of it thus.—We disapprove of this operation in synanche, as the excision is useless when all the air-passages and the lungs are affected. When, however, the parts around the mouth and chin are inflamed, or the tonsils obstruct the opening of the windpipe, it is a good practice to resort to pharyngotomy, (3) so as to escape the danger of suffocation. Then our procedure is to cut through a part of the trachea, at the third or fourth ring below the head of the windpipe, for it is unsafe to divide the whole. This place is convenient because there is no flesh, and the vessels are far from the incised spot. Inclining then the head of the patient backwards, so that the windpipe becomes most apparent, we make a transverse incision between two rings, directing it so as to cut, not the cartilages, but the membrane uniting them. If the operator has less confidence let him cut the skin after extending it with a hook; then, having reached the pharynx, (3) if vessels come in the way they can be put aside and the incision struck in. Thus far Antyllus, who judged that the windpipe was penetrated by the wind coming out with a rush, and the voice being extinguished. After the danger of suffocation is past the lips of the wound are to be made fresh and united with string, the skin only being sewn without the cartilage: then for healing we use astringent drugs. If union does not take place we employ flesh-forming remedies."

All the Arabian physicians notice laryngotomy at more or less length, but it is plain that their acquaintance with the operation is due merely to perusal of the above directions. Rhazes (4) (Muhammad Ibn Zakariyah, Al-razi), indeed, who lived about 850 A.D., begins by stating:—"I say that I saw Anclisius, a physician, use a very severe method of cure in his treatment of kyananche, not to be employed unless death be imminent," &c., but the sense cannot be taken literally, as *Anclisius* is plainly only an Arabic modification of Antyllus, with whose description the rest of the passage closely corresponds.

Avicenna (5) (Hassan Ibn Abdallah, Ibn Sina), more than a century after Rhazes, alludes very briefly to section of the windpipe, but deals very fully with the kyananche as ordinarily recognised. One of his recommendations may be accepted as the epegegesis of the nearly similar sentence found in Hippocrates:—"And sometimes a cannula made of gold or silver or similar material is passed into the throat to aid respiration, and likewise when the constriction is great there is no excuse for not placing a cupping-glass on the neck. And sometimes strong compression with spatulæ helps dilatation for swallowing and breathing," &c.

Avenzor (6) (Abd al Malik Ibn Zuhri), who flourished about 1090 A.D. was more enterprising with respect to laryngotomy than his predecessors. He remarks:—"I have not included the cure of kyananche by making an incision in the lung-pipe, as large as the nostril or a little less, because it is very difficult, nor have I seen anyone in my time who practised it. But when I was a disciple in this art I wished to verify the statements of the moderns who say that Galen made no mention of this remedy, but they were wrong, for Galen, where he taught how to incise the peritoneum, placed also directions as to dividing the lung-pipe. On this account desiring to make an experiment, I took a she-goat and cut the skin, the membrane beneath, and the lung-pipe to the extent of a lupine. I washed the wound daily with honey-water, and when it began to heal with flesh, sprinkled it with fine powder of cypress nuts until it was well again. But as I never saw any one in my time who performed this operation, I am unwilling to be the first to introduce it."

Albucasis (7) (Khalaf Ibn Abbas, Abu al Kasim), the most advanced surgeon of his age and nation (about 1200 A.D.), translates, almost literally, the directions of Antyllus, on which he makes various comments in favour of the operation. He concludes by referring to the case of a female slave who came under his care for a suicidal wound of the throat, which only opened the trachea. He soon effected a satisfactory cure, and hence observes:—"I think myself authorised to declare that incision of the larynx is without danger."

So far then there is no unequivocal testimony, no circumstantially recorded instance, to prove that section of the windpipe had actually been performed; and it is quite possible that the proceeding had not only been conceived,

but had been improved theoretically (as happened afterwards) merely from anatomical considerations.

#### FOURTH PERIOD.—From the Death of Actuarius to the Death of Morgagni—About 1350 A.D. to 1771 A.D.

With the opening of this period we experience a complete transition, and at once enter the temple of modern science, whose ample portals receive a concourse of devotees representing almost all languages and nationalities. Taking up the threads of our subject in Italy about the time of the Renaissance, we shall gradually be carried, whilst following them up, into nearly all the countries of both hemispheres.

We shall here, however, have to allude to some authors of date long prior to the end of the last period, for the growth of the modern school of medicine began insensibly soon after the final overthrow of the Western Empire, and its foundations are to be sought for in the obscurity of the tenth or eleventh centuries. Salerno, (8) indeed, is credited with having possessed the first academy of medicine that arose whilst Europe was emerging from the darkness of the Middle Ages, and its consolidation, if not its establishment, is attributed to Constantine, an African Christian, who repaired to that city about 1050, after a pilgrimage of thirty-nine years spent in the East, where he imbibed from the master himself the doctrines and practice of Avicenna. During the succeeding two or three hundred years almost all European cities became centres for medical education. Commencing their work with a thorough study and practical verification of the ancients, especially Galen, the new school of observers soon became intent on original investigation, and extended their researches beyond the goal attained by their masters. The movement in advance, however, only becomes markedly recognisable by the early part of the sixteenth century.

*Anatomy.*—The first progressive anatomist we meet is Jacopo Carpi, called also Berengarius, Professor of Anatomy at Pavia about 1500. He first noticed that the arytenoid cartilages formed a pair, and described their junction minutely in his "Commentaries on Mundinus," published at Venice in 1521. Carpi's remarks on this point remained unnoticed, and a later anatomist had the credit of the discovery.

Andreas Vesalius of Brussels (1514-1564), Professor at the University of Padua (9) was a very industrious expositor by dissection of the larynx (10) as well as of other parts. With copious descriptions and nearly thirty woodcuts (11) he exhibits with great exactitude the cartilages and muscles of the larynx from different points of view. Yet his advance beyond Galen with respect to this organ lies chiefly in his accurate and realistic manner of displaying the parts previously noticed by the Greek writers. Thus, although he lays bare the arytenoid cartilages, they still figure as one piece, because he does not distinguish the tissues joining them at the apex and base from the cartilage itself; like Galen, also, he reckons the crico-thyroid muscles as four (first and second pairs). He sets down, however, as constant in man, a pair of muscles almost peculiar to oxen, stretching between the stem of the epiglottis and the hyoid bone, and, as occasional, another pair running obliquely from the upper end of the spine of the second (cricoid) cartilage to the inferior cornua of the thyroid cartilage. Remarkable on the ancients not having named the second cartilage, he speaks of it as the "innominate." (12)

Gabriel Fallopius (1523-1563), colleague of Vesalius at Padua, was the most observant anatomist of his time. He was reputed the first to sever the ligaments binding together the arytenoid cartilages, and to assert their actual duality. (13) In his writings the second cartilage is first regularly spoken of as the cricoid, (14) but from the casual way in which he employs this name it is evident that it had been gradually creeping into use. He describes the muscles of the larynx more correctly than Vesalius, particularly the thyro-arytenoid. Of this he says: "It arises from the internal and middle part of the first cartilage (thyroid), but in its whole length, and as it has a triplex origin, it gives the impression of three muscles." He finally disposes of the error perpetuated from the age of Galen as to the crico-thyroid muscles being divisible into an internal and external pair. On this point he remarks that Vesalius must have been deceived by observing through the crico-thyroid space the fibres of the muscle inside (thyro-arytenoid). The stylo-thyroid muscles first appear in this author.

Fabricius of Acquapendente (1537-1619), pupil and successor of Fallopius, was a diligent student of comparative

anatomy; and especially an ingenious theorist. He devoted an ample treatise (15) to the description of the larynx in man and animals, and gives many details not referred to by his predecessors. Thus he mentions that the glottis is composed of "cartilage, muscle, and membrane," but he seems to think that the latter in man, as in the sheep, pig, &c., has a fatty nature. Though he does not describe the human ventricles, he points out their extent, with the manner and situation in which they terminate, in the pig and horse. He also notices most definitely hitherto the distribution of the recurrent nerves, stating that they each divide into three branches, respectively for the second, third, and fourth pairs of muscles (posterior and lateral crico-arytenoid and thyro-arytenoid). His work is fully illustrated with lucid copper-plates, and here the thyro-hyoid ligament is delineated for the first time. It may be remarked that with all the writers of the present period, conformably to Galen, the vocal bands are called "the glottis," and the space or fissure between them the "rima glottidis."

Caspar Bavhinus (1550-1624), Professor of Anatomy and other subjects at Bâle, is the author wholly or in part of a very important advance in laryngology, viz., the nomenclature of the laryngeal muscles. In 1597 he enumerates (16) five pairs of intrinsic muscles, as the crico-thyroidei, antioi, and postici, the cricoidei laterales, the thyroidei interni, and the arytenoidei; but eight years later (17) he describes the three pairs of extrinsic and the five pairs of intrinsic muscles precisely under their modern names. As the general method of nomenclature of the muscles first appears about this date, we may assume, in the absence of any special claim in the case of Bavhinus, that the names had long been creeping into colloquial use as part of a system initiated by some unknown anatomist.

Julius Casserius of Placentia (1545-1616), pupil and successor of Fabricius at Padua, is the author of a most comprehensive work (18) on the anatomy and physiology of the larynx, human and comparative. In twenty folio plates delicately engraved on copper, and accompanied by a copious and erudite text, he exposes the larynx and all its parts in man, quadrupeds, and birds. Apart, however, from the superior accuracy of his drawings, which are far more numerous and true to nature than those of Fabricius, and almost equal to the best produced in recent years, I am unable to credit him with much positive addition to the anatomy of the human larynx. The hyo-epiglottic ligaments first appear in one of his plates, and we may therefore allow him to have discovered it, and probably also the glosso-epiglottic ligament. Casserius makes a slight allusion to Bavhinus and his suggestions as to nomenclature, but does not adopt it in his great work. In a posthumous edition of his anatomical plates, (19) however, published in 1632, all the laryngeal muscles are designated by their present names.

Thomas Willis (1621-1675), Sedleian Professor of Natural Philosophy at Oxford, furnished us with the first definite descriptions (20) of the spinal accessory and superior laryngeal nerves, which were almost disregarded by previous anatomists. Describing the filaments of origin of the pneumogastric (already the eighth pair) he remarks:—"In man they are at least twelve, some larger, some smaller, to which is added a noted fibre, or rather nerve from the spinal medulla, much greater than the rest. Joined to them and invested with the same tunic derived from the dura mater, it emerges from the cranium, as if all had coalesced into one trunk. But that accessory nerve, and also many other fibres, still remain distinct under that investment, and afterwards dispersing, are borne into peculiar provinces. Speaking of the pneumogastric ganglion, he says that from it "a noted branch being sent forth is carried towards the larynx and divides into three shoots, the first of which extends into the sphincter of the gullet; the second, being buried beneath the scutiform cartilage, gives its offshoots to the superior muscles of the larynx, and to those which shut the fissure of the larynx; and the third, also going under the scutiform cartilage, runs towards the apex of the recurrent nerve, and is united with it."

After the time of Casserius more than a century elapsed without any special work being undertaken with respect to the larynx, but at the beginning of the eighteenth century we are recalled to Padua by John Baptist Morgagni (1682-1771), the last and the greatest of those celebrated professors who rendered that University the leading medical school of Europe. This remarkable investigator, the Galen of modern times, may be regarded as the second founder of

laryngology, so completely did he initiate and reconstitute the study of the subject as it is pursued at the present day. Morgagni (21) was the first to notice the posterior or oblique fibres of the arytenoid muscles. He was also the first to dissect out and describe the cuneiform cartilages, but he brings them forward under the name of "arytenoid glands," having erroneously determined their nature. The epiglottic glands, the pharyngo-epiglottic ligament, and the superior vocal ligaments (ventricular bands) owe their recognition in anatomy to the researches of Morgagni. By him, again, the ventricles of the human larynx were first definitely examined and described, and as these cavities are generally associated with his name, we may appropriately reproduce some of his remarks on them. "Between the two ligaments I have brought under notice a fissure is left on each side, almost of an elliptical figure, of such length that the apex of the thumb or of a finger, according to the size of the larynx, can be inserted. The fissures are the orifices of cavities, the inferior part of which is bounded by the lower part of the thyro-arytenoid pair of muscles. Behind, to a moderate height, they are covered by the middle and superior fibres of the same muscles, but above they have the shorter limbs of the arytenoid glands to a certain extent, for when they approach the base of the epiglottis the cavities are higher, as an appendix of greater or lesser size is there added to them, which can easily be observed by introducing a style. The walls of the cavities are invested by the same tunic as that which covers the interior of the larynx, whence they are perforated by many small foramina, especially where the limbs of the arytenoid glands are near, from which foramina small drops of a thick lubricating humor proceed." Finally, Morgagni restored to notice the stylo-thyroid muscle and the glosso-epiglottic ligament, which had been lost sight of since the time of Fallopius and Casserius.

With John Dominic Santorini (1681-1737), Professor of Anatomy at Venice, the scene shifts finally from Padua. Later in his researches, though much earlier in his death than Morgagni, he extended some of the observations of the latter, and discovered the *capitula* which bear his name. (22) "These," says he, "which we shall name for the future the *capitula* of the arytenoids, are often joined to the arytenoid cartilages by a loose, though sometimes by a rather firm binding, in such a way, however, that they may clearly be seen to be superadded, and not continuous. Their base, which is in apposition with the obtuse vertices of the arytenoids, is slightly hollow, so that it may easily and suitably fit the top of the convex vertex to which it is joined." He remarks also that these *capitula* are moveable not only in youth, but in age, and conjectures that their articulation is provided with a propersynovial cavity. Santorini first traced the oblique muscular fibres which cross the arytenoid cartilages posteriorly in their course forwards and upwards to the epiglottis, and also the fibres passing from the apices of the same cartilages forwards and downwards to the thyroid cartilage. The first set of fibres he named *ary-epiglottidæ*, and the second *thyro-arytenoidæ obliquæ*. In addition he described two pairs of inconstant muscular slips between the epiglottis and thyroid cartilage as the *thyro-epiglottidæ*, *maiores et minores*, and he observed with greater minuteness than previously the remaining laryngeal muscles, especially the superior (now external) thyro-arytenoids, and the ligaments. Like the other anatomists of his time, he elucidates his investigations with copper-plates.

(1) Latin versions of all these authors were made and published, some at Venice, others at Leyden, in the 15th and 16th centuries.

(2) L. vi. c. 33.

(3) The vagueness in applying the word pharynx, larynx, and trachea never wholly disappeared amongst ancient medical writers.

(4) Continens, Venetis, 1612, L. vii., tr. ii., c. 2. "Dico quod vidi Andilium medicum, &c." are the words in the translation of Surianus.

(11) So Mundinus, the most primitive of the modern anatomists (about 1300) in his scanty treatise (Anatomia Marpurgi, 1540, vol. 46), says it is called "Nomen non habens." The anatomical tables of Eustachius, an earlier writer than Vesalius by, perhaps, a score of years, "rescued from darkness" as the title-page states, contain good illustrations of the larynx (published at Rome, 1714), but, they seem to have been worked up to date by the editor Lancisi.

(12) *Institutiones Anatomicae*, cap. de Thorace (Opera Omnia, Francofurti, 1606, T. I., p. 444). Yet Maass many years previously applied the epithet "bipartite" to them (*Liber Introductorius Anatomicae*, Venetiis, 1586, fol. 65); and Vesalius also, in the later part of his work, calls them "duplex," though in a manner suggesting that he had not observed it for himself. Santorini, however, expressly states that Fallopius was the first who "easily detected and demonstrated" this fact. But the language of Fallopius makes no claim to the discovery, which really belongs to Carpi.

## Clinical Records.

### CASE OF STRICTURE OF THE MALE URETHRA IN WHICH COCAINE WAS USED WITH SUCCESS.

Under the care of Dr. G. DE GORREQUEER GRIFFITH, Physician to the Hospital for Sick Women and Children, Pimlico.

IN several affections of women I have found this drug a valuable local anæsthetic when applied by means of painting it on the part, or soaking a piece of absorbent wadding in it and laying it on the tender spot, or injecting it subcutaneously. In a case similar to the one to which I am about to refer I have not before used it; nor do I know of any such case on record.

Mr. F., husband of Mrs. F., a private patient, came to me some weeks ago completely broken down in mind, and his nervous system so shattered that his wife had been informed he would soon have to be placed in an asylum. Finding he had been ordered brandy and suchlike stimulants, and that he was suffering from sexual depression, I at once discontinued the stimulants, and put him upon a tonic with sp. am. co.; the sleeplessness of which he complained was cured by bromides at night.

On examining the penis I found the urethra at the orifice closed so much as only to admit the tip of an ordinary probe, the admission having to be made by force and with great pain to the patient. I thought it would be necessary to slit up the orifice. As he had a dread of chloroform I dilated with the probe first, then, with some amount of force, I dilated still more with No. 3 silver catheter; then, after a few days, with No. 5. As he experienced great pain, I resolved to use the cocain. For this purpose I soaked a piece of absorbent wadding, wrapped round the probe, in a 2 per cent. solution of the cocain, passed it rapidly through the orifice for extent of 1½ in. into the urethra, any drops which regurgitated being smeared over the end of the penis. The probe—coated as I have described—was left in for about 5 min., and on removal I passed in rapidly a silver bougie graduated from 8 to 11, and left it in the urethra up to the hilt, and thus painlessly dilated the orifice up to No. 11. No pain was experienced along the urethra till the bladder was neared. I might say that there were no children the issue of the marriage, that intercourse had always been pain rather than pleasure; that, in fact, he had dreaded coitus, partly because of the pain at the time and partly because of the extreme prostration afterwards. I assured him that unless something were wrong with his wife, it was possible for him to be a father, assuming that the spermatozoa were present, and that he need not now have the dread which formerly haunted and oppressed him.

He has told me that he feels quite well, better than he has for years, and that there is no inconvenience whatever experienced by intercourse. I used the expression to him "that unless something were wrong with his wife it was possible for him to be a father." I used it advisedly; because often in these kind of cases, owing first to imperfect, or incomplete coition, and secondly, to non-conception, there is evolved, as a consequence, the conoidal cervix with pinhole os, and with hyperplasia and hypertrophy, which are bars to conception, even if there be no endocervicitis, which often obtains

in such cases. The orifice will now admit No. 12 without any pain, provided the cocain be employed.

## Transactions of Societies.

### ACADEMY OF MEDICINE IN IRELAND.

SUB-SECTION OF STATE MEDICINE.

MEETING HELD THURSDAY, MAY 14TH.

The President, Dr. J. W. MOORE, in the Chair.

### RELATIVE DISEASE AND DEATH-RATE IN TOWN AND COUNTRY.

THE REGISTRAR-GENERAL (Dr. GRIMSHAW) gave a *résumé* of his paper on the relative prevalence of disease, and on the relative death-rate in town and country districts.

The PRESIDENT regarded the remarkable coincidence between the average disease and death-rate as one of the strongest arguments that could be adduced in favour of the registration of disease.

Dr. JACOB asked how far these interesting and important facts ought to be discounted by the deficiencies of registration, because the curves on the charts, even on a cursory view, revealed certain points which he should not have expected. In diagram 2, for instance, he found that Dundalk was the most healthy district in the whole of Ireland, the death-rate from zymotic diseases being down to 22, from phthisis to 16, and from diseases of the respiratory organs to 32. But he never understood that there was anything specially salubrious about the Dundalk district, and therefore he apprehended there might be influences at work to disturb the mathematical accuracy of the diagrams. Again, in Derry there was an inconsistency in registering under phthisis and diseases of the respiratory organs a death-rate of 20, whereas for phthisis the registered death-rate was 20. Accordingly, he asked how far it was probable that the want of efficiency in registration might affect the curves.

Dr. HENRY KENNEDY emphasised the extreme value of the Registrar-General's information and remarks. The fact had been long established that the towns were less healthy than the country, and there was a perceptible difference, too, in favour of the healthy appearance of the country population, townspeople being more or less pallid. He mentioned that an American writer had discovered a particular fungus that generated measles, and asked whether the epidemic in Belfast was due to flax and materials used in the linen manufacture. It was proved that bad straw generated camp measles. Another cause for the measles in Belfast was that the rainfall there was greater than in Dublin. He had no doubt that a dry climate had an important bearing on health; for instance, people who went to reside in England at once lost rheumatism with which they were afflicted here. The registration of the causes of death depended on the professional knowledge of the medical men in each locality, and he had no reason to believe that facilities of knowledge differed in one place more than another.

The REGISTRAR-GENERAL, in reply, observed that the greater portion of Belfast stood on very damp ground, whole streets being built on piles, while Lisburn and Lurgan were on comparatively dry sites. A great portion of the soil of Belfast was very wet and sticky, and the amount of sun and light required to make ordinary plants grow was astonishing. Within his own recollection parts of Belfast where houses now stood were covered by the sea. At the same time, the people in Dublin who lived in fourth-class accommodation numbered 44 per cent., or very nearly half the population, while in Belfast only between 6 and 7 per cent. lived in tenement houses. House accommodation had a great deal to do with the death-rate. In the country the people looked on houses more as a shelter from bad weather or for the night than as habitations, the doors being always open. He did not at all accept the flax origin of the measles, since from the way flax was worked there could never remain any quantity of mouldy material, although there was a good deal of decaying woody fibre in the preliminary stages of steeping and drying of the flax. That process, however, was not connected with the mills, and was carried out before reaching the mills. No doubt there was a vast deal of dust

in the mills, but not musty dust. Therefore, it was unlikely that measles would arise to any extent in connection with flax manufacture.

Dr. JACOB read a paper against

THE COMPULSORY NOTIFICATION OF INFECTIOUS DISEASE  
BY MEDICAL MEN.

Dr. FITZPATRICK concurred in Dr. Jacob's observations that the medical profession would be placed in a most invidious position, without any possible good arising to the public. Some years ago he was called by a professional brother to visit two children in one of the most fashionable schools of Dublin. Measles broke out. The husband of the lady who kept the school said he feared she had contracted the disease. Having seen the lady he found she was suffering from scarlatina. Her husband said if that went out they were ruined for life. Under the circumstances he said if his directions were strictly adhered to he would preserve the rest of the house from contagion. The husband having promised, the lady was removed to the top story of the house, and it was arranged that the nurse should never leave the room, and that every article should be placed in chloride of lime. The patient recovered, and not another soul got the disease. Thus the reputation of the school was preserved, and had he acted differently it would have been destroyed. In another case he was called upon to see a child at Kingstown. The mother had left the child in perfect health, but it was subsequently attacked with vomiting and convulsions. His impression was that it was scarlatina, but there had been no eruption or sore throat. In three or four days the whole family became attacked, including a young lady on a visit, who was taken away and died of the disease. He caught the disease himself, and brought it into his family. His wife and servants all got it, and he lost one of his children. For three months no person approached his house. By managing properly and procuring isolation the spread of the disease could be prevented.

The REGISTRAR-GENERAL (Dr. GRIMSHAW) differed from Dr. Jacob in everything he said, being strongly in favour of compulsory notification. Two questions were mixed up which should be separated—one whether there should be compulsory notification of disease, and the other whether the medical man should have any responsibility in the matter direct to the sanitary authorities. That notification would tend to prevent and diminish disease he was certain, and the two instances Dr. Fitzpatrick recounted supported his view. The first was one where he was able to isolate and prevent the spread of the disease. There there was no publication. The other was one in a private house. The disease spread, how much it was hard to tell, except that Dr. Fitzpatrick brought it home. That Dr. Fitzpatrick's profits were for a time diminished was an unfortunate circumstance, but if that prevented the public getting the disease, *caedet quantio*? He had had the disease himself twice in his house. On both occasions he warned his neighbours. The first thing he ordered the servant to state at the door was that he had scarlatina. No doubt he lost a good deal of money, but he did not regret it; for when he looked back on the terrible infliction himself, he would not, for all he possessed, have allowed the smallest chance of scarlatina being carried from his house to any one else's house. People complained individually of the losses inflicted on them, but the losses inflicted on others who caught the disease, were just as great or greater, and on moral grounds, independent of anything else, nobody had a right to inflict the misery. With regard to the figures brought forward, having read all that had been quoted in some shape or other before, he was bound to say he never could discover anything to show that injury had been produced by the notification of infectious disease. On the other hand, the sanitary authorities, knowing that a particular disease existed in a particular place, could take precautions to prevent its spread, and thereby benefit the community. But where the sanitary authorities were unable to interfere the disease had spread, destroying numbers of lives, and creating misery among the working classes, who were deprived of every penny they had. He knew of an instance in Christchurch Place where, owing to the authorities not interfering sufficiently early, the disease spread to five houses, resulting in four deaths and thirty-five cases of typhus fever. Had the existence of the disease been known, and precautions taken in the first instance, there would have been only three or four cases, instead of thirty-five. The loss of Dr. Fitz-

patrick's fees was as nothing compared with the loss that those poor people suffered; they were absolutely ruined. Disease broke out in a house in St. Michael's Lane, and in another in Christchurch Place, each becoming a centre of half a dozen cases of typhus fever. Take South Lancashire, one mass of houses—if disease broke out in one house it spread to another, and therefore unless the system of notification applied to the whole of South Lancashire and the greater part of Yorkshire it would be worthless.

Dr. FITZPATRICK protested he had made no concealment of the presence of disease in his house, nor was it necessary, the existence of the disease being patent to all his neighbours.

Dr. COSGRAVE having had practical experience of the working of the Act for two years in Huddersfield, pointed out that at least two of the objections urged against it did not amount to anything. One was that the voice of the profession was not heard against the Act. But if found prejudicial by others than dissenters accustomed to air facts, no matter how destructive to the health of the population, the voice of the profession would be heard. Although the severity of the Act had been increased in Huddersfield, he did not find his brethren there complain of having to carry out its provisions. During his time it was strictly carried out. But it was quite right that certain cases need not be notified; for instance, where a case can be isolated and treated in the house. That was a definite common-sense rule obviating any difficulty. With regard to the loss of money, in the majority of cases where the people were able to pay medical men the patients could be treated in their own houses. But it was different with the people who lived in tenement dwellings, who were not a paying class of patients, and if those cases were moved into hospital, as they should be, the dispensary medical officers would have a much easier time of it than at present. With regard to the figures, it should be borne in mind that where the mortality was represented as one in four in epidemic, there might be a number of cases in each house, and that, therefore, the mortality might run up to one in sixteen or one in twenty. As to imposing a penalty, he did not see how the principle differed from that of imposing it for not certifying the disease of which a patient died. He had himself opposed notification in the first instance. The best mode of notification was to hand the form filled up to the person in charge of the case, whose duty it was to transmit it, and therefore it could not be said the medical man went behind backs to notify. He thought that preferable to the present mode of direct notification. At the same time he concurred in Dr. Jacob's appeal for an investigation into the working of the Act, the question involved being one affecting the health and life of the population. He believed that notification struck at the root of infectious disease.

Dr. HENRY KENNEDY inclined largely to Dr. Jacob's views, and regarded the evidence which he adduced as conclusive.

Dr. EDGAR FLYNN, speaking from experience of the working of the Act in Leicester and Nottingham, believed that a measure for notification of disease would be of no great harm. The system of asking medical men to fill up and send in the forms when a case of infectious disease came within their notice worked very well, and they received a fee of 3s. 6d. During the last two or three months there had been a very serious epidemic of scarlatina raging within a radius of two miles of Kingstown, but no notice had been taken of it by the medical officers of health, of whom there were six or eight in the district. When he inquired what was being done, the answer was a profession of ignorance and a reference to somebody else. He agreed, however, with Drs. Fitzpatrick and Kennedy, of the great hardship of asking medical men to become detectives, and therefore that the measure should not be compulsory.

The PRESIDENT avowed himself to be strongly in favour of the compulsory notification of infectious disease. The relation which the profession held to the State, or rather to the people of the country, should be remembered. The licensing bodies were acting under charter, and likewise the universities existed by the favour of the State, and, therefore, anything ordered to be done by the profession must be done, grumble and protest as they may. He regretted that Dr. Jacob should have given the character he did to some members of the profession, and he could not believe there were men in the profession who, when they deliberately recognised a case of scarlet fever, would set it down as one

of nettle-rash, or non-infectious disease, or state they did not know what it was. At any rate, whoever did such a thing should be brought under the censure of his college or university, and deprived of his qualifications. A much more unpleasant duty was imposed upon the profession when medical men were asked to certify the cause of death, in which privilege should be presumed to exist to a greater extent. Dr. Jacob had drawn purely fancy pictures of the existing state of affairs. He had mentioned that the Act had led to concealment of disease, forgetting that, in towns where it was not in force, greater concealment prevailed. It was notoriously the case in Dublin. Speaking from a greater experience than Dr. Jacob's of the prevalence of infectious disease and its concealment, he knew it was dreadful. While they meddled and dabbled here and there in tentative experiments, no good would result. What they wanted was a code making infectious notification applicable to the whole country, rich and poor, but with modifications. A difference would be made in the treatment of rich and poor patients to the end of time. He approved of an inquiry as happened in reference to the Public Health Act.

Dr. JACOB replied—The Registrar-General had entirely misunderstood his purpose and his views. It was not the notification of the existence of disease to a sanitary authority he deprecated at all, but the proposition that such notification should be effected through the agency of the medical profession; because he held that the beginning and end of the concealment of disease, and the consequent dissemination of infection, would be the exclusion of the medical man once he was forced to act as a detective. The argument of the suffering to individuals he passed by; individuals must ever suffer for the good of the community. Personal loss, therefore, had no element of argument for him, except so far as the individual was induced to conceal disease to avoid that loss. In fact, the whole pivot on which this argument turned was the concealment of disease from the sanitary authority. Where there was a medical man to the fore to give good advice and see it carried into effect, the concealment of disease was of comparatively little importance; but the concealment of disease where there was no medical man in the case was fraught with every element of destruction to the community. Dr. Cosgrave had said that if this grievance were so bad as represented the medical profession would have spoken out. The profession had spoken out as far as the circumstances allowed. Notification was sought to be imposed in Brighton by smuggling the clause into a harbour bill; but he sent a marked copy to those interested, and the bill was defeated. The same observations applied to Edinburgh and other places. Opposition had been given in several instances. But when the Select Committee on Private Bills was struck, it contained a majority in favour of compulsory notification, and so a hearing was refused to Dr. Alfred Carpenter, who offered evidence on behalf of the profession to show the working of the system failed to produce the results aimed at, the reason assigned being that no evidence could be heard except from the towns to which the bills related. Therefore it was not to be said the judgment of the profession had been heard or pronounced. Death certificates were utterly fallacious, and concealment was the practice wherever the incentive existed; for instance, syphilis and delirium tremens were represented by such euphemisms as spinal irritation, urinary disease and debility; and often certificates were given, not for the disease which actually killed the patient, but for the symptoms, and the true cause of death being assigned only in the case of paupers. He affirmed that the Act which had been working for seven, eight, or nine years in twenty-two towns had utterly failed to produce any amendment of the public health, and, therefore, he asked the Academy to take a prominent position to prevent the further extension of it.

The sub-section then adjourned.

#### EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

THE last meeting for the current session was held on the 22nd July,

The President, Dr. LITTLEJOHN, in the chair.

#### A CASE OF LAPAROTOMY.

Professor CHIENE exhibited several patients of clinical interest. The first was a man on whom he had performed

laparotomy some weeks before on account of intestinal obstruction. For a day or two after admission to hospital the patient's symptoms had not been alarming, and Mr. Chiene had tried all the ordinary methods with a view to preventing the ultimate necessity. A sudden accession of symptoms, however, made him decide to operate. On opening the abdomen the intestines protruded freely, and it was only after carefully following the small intestine downwards that he was able to discover a knuckle of bowel crossed on itself and held down by a thin band of tissue. Mr. Chiene could not say whether or not this had existed the whole time patient had been in hospital, and whether the accession of symptoms had been due to the tightening of the bridle band. He ligatured the extreme ends of the band, and cut away the intervening tissue. There was comparatively little difficulty in returning the intestines. In sewing up the abdominal walls he used catgut for the deeper, and horse hair for the superficial sutures, bringing out the long ends of the catgut to admit of drainage. Though the patient was suffering from a troublesome cough, the recovery had been rapid and complete. The Society could satisfy itself as to his convalescence.

#### AN INTERESTING BRAIN CASE.

The next patient was received into his ward on account of staggering, uncertain gait, apparently due to weakness of the left leg. There was a history of injury to the head, and examination revealed the presence of a tender point over the region of the right posterior parietal lobe. Other symptoms of nervous disturbance were present in addition, especially great exaggeration of the patellar tendon reflex and dimness of vision. After consultation with the physicians Mr. Chiene, believing that in some way the centre for the opposite leg and foot was disturbed, determined to trephine over the tender area. On removing the piece of skull nothing abnormal was detected, the bone appearing natural. The dura mater was then incised, and about two ounces of serum, containing a marked increase of leucocytes, came away. He could not say whether this were a localised and possibly encysted collection of fluid or indicated an excess of subarachnoid fluid. Certainly the increase in the leucocytes suggested something inflammatory. The result of the operation justified the diagnosis and the line of treatment. The patient had no bad symptoms, and now he walked firmly and well, and all trace of exaggerated tendon reflex had passed away. Dimness of vision was still present.

#### FOREIGN BODY IN BRONCHUS.

The last case was that of a man, who came to him some years ago, professing that a half sovereign had gone down his throat. After excluding every other possibility, Mr. Chiene performed laryngotomy and inverted the patient, but to no purpose. The wound was, therefore, allowed to heal, but ever since the patient has maintained that he feels the coin lying somewhere on the right side, and that it moves from time to time. Mr. Chiene added that medical examination gave no clue as to its presence in one or other bronchus, and as the patient was little inconvenienced, he had to discharge him, while still uncertain as to the facts of the case.—The President suggested that four physicians should examine the case minutely that evening. Accordingly Drs. Affleck, Smart, James, and Russell Wood retired with the patient for a consultation. Their verdict was, as before, negative. In connection with such cases, Prof. Chiene held strongly that laryngotomy or tracheotomy should always be performed prior to the inversion of the patient.

Mr. Chiene exhibited a large and interesting collection of foreign bodies which had been removed from the pharynx and air passages, either by the late Prof. Spence, or by himself, all of which were now in the very rich surgical museum of the University, of which he showed them the newly-completed catalogue. The collection included beads, fruit stones, keys, handkerchiefs, coins, teeth and tooth-plates, portions of meat and bones.

Mr. C. W. CATHCART brought under their notice a

#### NEW MATERIAL FOR MAKING ANATOMICAL CASTS.

It had the merit of reproducing in a most delicate way the natural appearance of the skin. A few touches with water colours enabled them to represent faithfully any pathological lesion. It was specially well adapted for the representation of superficial alteration, such as chancroids, condylomata, ulcers, lupus, &c. He showed a number of re-

productions already prepared by himself. The constitution of the material was as follows:—Glue or gelatine (1), 1 oz.; glycerine, 1 oz.; water, 2 drms. A plaster cast is first made, and then this material, in liquid form, is poured over the cast and allowed to cool.

Dr. F. W. CAIRD exhibited a large number of

ENTIRE SECTIONS OF TUMOURS OF THE TESTICLE,

cut by Dr. Bruce's large freezing microtome. Several of these were injected and beautifully stained. They compared very favourably with those he had previously shown, cut by hand. They were so thin as to be adapted for microscopic work, the only desideratum being a microscope with a large enough stage.

Dr. ALLEN JAMIESON wished to make the members acquainted with a series of new soaps, introduced for the treatment of skin diseases by Unna, of Hamburg. They were known under the name of "Ueberfettigte Grund Seife," and the important feature was the presence of a certain amount of free fat, which acted as a softening and protecting agent in the treatment of certain skin diseases.

The PRESIDENT thereafter congratulated the members on the great success of the session which they were just bringing to a close. There were abundant signs of vigorous and fresh life in the medical school of Edinburgh. The Society adjourned till November, 1885.

## Department of Lunacy.

### LUNACY LEGISLATION.

#### [SIXTH ARTICLE.]

WHETHER the axe of legislative reform is to be applied to the root or the branches we know not, for a well-timed though ill-advised legislative effort is now in great danger of coming to an untimely end; and a second measure may have no likeness to the first. Be such as it may certain dogmas stand out crisp and clear, which may determine the direction in which local as well as political energies should run. The first of these is that classification of the insane for administrative purposes is an imperative necessity. The reckless extravagance which has characterised certain local bodies in providing asylum accommodation is a blot on the escutcheon of the voluntary unpaid public service. Crowds of human cyphers *sans* all but vegetative existence are herded amidst expensive surroundings, called lavish and beautiful, without a shadow of additional return medically or otherwise. This is bad enough, but the fraction of susceptible human elements, scattered in the crowd are planted amidst the same surroundings *plus* the repulsive, depressing, and degrading chronics with literally no discriminating, structural, moral, or individualising treatment. The money promiscuously expended on recent and chronic lunacy has been more than enough to provide for structural arrangements, suited to separate methods of treatment. From such a false step at the outset springs a multitude of subsequent errors of administration which are necessary and logical sequences. There never is, and never can be under such circumstances, that nice adjustment of means to ends, and of individual treatment to individual necessities, that a scheme of structure graduated according to classification will provide. The measure of supervision has to be roughly estimated, and this implies irregularity in the efficiency of control. The healthy and the weak, the curable and incurable, in short, patients of endless variety of mental and physical habit are put through the same mill of routine, under the name of lunacy treatment. As we have already indicated this must now be borne in patience. Structural blots are not to be wiped out by a stroke of the pen, and we cannot look for miraculous transformations by which old things pass away and all things become new. The rapid increase of registered lunacy will, from time to time, afford oppor-

tunities in many localities for rectifying, in whole or in part, old inapt organisations, and wedging in details of hospital method and construction of a definite and distinguishable kind.

Whether the doctrine of evolution is visible in the history of lunacy, or whether it is that the range and acuteness of observation are greater and bring into relief features previously undetected, the conclusion is obvious, that in the present day generalisation is becoming more and more limited to sections of the insane community. Varieties of the unsound mind are superabundant, and indications for somatic treatment are now frequent and more apparent. Deviations from the usual standard of mental health are recognised as coming within the scope of the lunacy laws, with a pertinacity that is alarming when we consider that bodily health is for some time below par, and as an out-come of it, peevishness, suspicion, apprehension, indolence, excitability, irritability, delirium, and a host of mental manifestations of the finest morbid shades form the *raison d'être* of lunacy treatment. An increasing flow of what are pure and simple hospital cases surge into asylums under the name of lunacy. Are our nursing sisterhoods and trained nurses in the hospital wards of workhouses unequal to the task of such peculiar care? It is passing strange that it should be considered that asylum attendants alone possess the mental and moral qualities necessary for such a charge. We see cases in asylums no worse than we have often seen in hospitals and workhouse infirmaries; it is not surprising then that for such a class a more perfectly equipped hospital system is necessary in Asylums? And if for them how much more extensively for acute cases labouring under prostrating bodily disease, for paralytics, puerperal and allied cases, the aged and infirm and many others. In conjunction with this we require to realise a higher ideal of observation, individualisation, and treatment for new cases of all kinds, to remember that the primary object of lunacy treatment is cure, that when all else fails, care must be the chief objective, and that the relative equipments for these are widely different, and require broadly discriminative, structural, and administrative details. The indiscriminate and wholesale confinement within the same walls of all sorts and conditions of insane men and women, has been a great blot on our lunacy record, and the sooner this is recognised over the length and breadth of the land, and the sooner classifications on the lines which we have indicated become the object of lunacy reformers the better for the country in every respect.

### INSANITY IN CALIFORNIA.

Dr. W. H. MAYS, Physician to the State Asylum for the Insane, Stockton, Cal., in an article contributed to the *Pacific Medical and Surgical Journal*, June, 1885, makes the announcement that since 1876 the number of persons committed as insane has remained almost at a standstill. In 1876, with a population of, in round numbers, 700,000, the commitments aggregated 735. In 1879, with a population augmented to 800,000, the commitments were 721. In 1882, with a population of 900,000, there were but 722 commitments, and in 1884 the commitments were 764. In 1876, 735; in 1884, 764. Taking the ratio according to population, in 1876, one person in every 950 was seized with insanity; in 1879, one in every 1,100; in 1882 one in every 1,250; in 1884 one in every 1,300.

Dr. Mays notes, as one cause of the continual need for increased accommodation for the insane, in States where the population is increasing, which is worth bearing in

mind, *i.e.*, the remarkable longevity of the chronic insane and the steady accumulation of such cases. This longevity on the part of the insane was commented upon by Esquirol sixty years ago. Idiocy, however, is extremely rare in California.

Amongst the causes which tend to diminish insanity in California, Dr. Mays believes the following to be the most important:—"The higher wages paid to working men, the shorter hours of labour, the greater amount of leisure they enjoy, the better education they receive, leading them to put that leisure to more intelligent use, the better houses they live in, above all the better food they eat, supplying the proper nutrition of body and brain—all give us hope that, as years and generations go by, insanity will become less and less the formidable thing it is. Dr. Mays makes a strong appeal for the regular instruction of students of medicine in the study of mental disease and its treatment, seeing that about 1 in every 400 persons has his mind affected in some form or other; that many cases have to be treated at home; and that many cases need not be sent to the asylum at all. Not only this, but as Dr. Clouston, of Edinburgh, points out, the early recognition of mental disorder, the detection of its forerunning symptoms, and their treatment, the mental hygiene of those with a neuropathic history, and the question of a career in life, the capacity for making a will, the responsibility for a criminal act, and lastly the examination of those charged with insanity, which often falls to the lot of the country practitioner, involving the serious question of depriving a fellow-citizen of his personal liberty—these are matters that a physician should be fully competent in before he can be said to have had a proper medical education. And this is not to be reached without systematic clinical teaching." This appeal is both reasonable and in accord with the dictates of sound common sense.

#### THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE annual general meeting will be held in the Examination Hall, Queen's College, Cork, on Tuesday next, Aug. 4, under the presidency of J. A. Eames, M.D., F.R.C.S.I., when Dr. Rayner will resign the chair, officers for the ensuing year will be appointed, and the general business of the Association proceeded with. Among other matters of interest a recommendation of the Council in regard to the granting certificates in psychological medicine by the Association will be brought forward, Dr. Eames will deliver an address, and Dr. Hack Tuke will read a paper on "A Case of Moral Insanity." Dr. Charles Nicholls, of the Bloomingdale Asylum, New York, will be proposed as an honorary member, and Dr. H. G. V. Wharry as an ordinary member. The members of the Association will dine together after the meeting, and those intending to be present are requested to give notice to the Hon. Gen. Sec. prior to the meeting. Any members wishing to join an excursion to the Lakes of Killarney, starting on the day after the meeting, are requested to communicate with Dr. Courtenay, District Asylum, Limerick.

WE understand that the Conjoint Examination Scheme which has been under discussion between special committees of the Irish Colleges of Physicians and Surgeons has been finally adopted by the joint committee, and will be presented to the Colleges next week.

DR. PH. S. ABRAHAM has resigned the office of Curator to the Museum of the Royal College of Surgeons in Ireland, it being his intention to accept an offer of a similar appointment in London.

## France.

[FROM OUR OWN CORRESPONDENT.]

**RUPTURE OF THE URETHRA.**—At the meeting of the Société de Chirurgie M. Ferrier brought forward a case of rupture of the urethra, producing infiltration of urine and fistula, and no means of closing the wound in the canal. He was of opinion that no further operative interference should be resorted to, that the man should be allowed to micturate through the fistula, but he would be glad to have the advice of his colleagues. M. Tillaux in a similar case incised the perinæum the day of the accident, and succeeded in passing the catheter every day, the patient made a good cure. M. le Fort said he had a case in which he passed the catheter the moment after the rupture, and he left it *in situ* for two months, but in spite of all a stricture took place, and he had to perform external urethrotomy. M. Gillette said that he thought it bad practice to pass the catheter immediately after the accident, for it was not well tolerated, and another member said he never introduced it until after the tenth day.

**RESECTION OF THE STERNUM FOR RETRO-STERNAL ABSCESS.**—M. le Fort communicated an interesting case of resection of the sternum for retro-sternal abscess in a man of middle life. The general state of the patient was very grave, death being imminent from suffocation. Two inches and a half of the bone was resected, and a considerable amount of pus evacuated. The patient, who only consented to the operation with the hope of dying under it, refused all nourishment and tore off the dressing several times. On the third day he died, and the autopsy showed that operation was well done, the mediastinum not being in any way interfered with.

**CANCER OF THE UTERUS.**—M. Tillaux brought under the notice of his colleagues a case of cancer of the womb in a woman, *æt.* 21, for which he practised hysterectomy. The abundant hæmorrhage and the general condition of the patient induced him to operate. The *cul de sac* were free, and the uterus was easily brought to the vulva by hooks. A sound being placed in the bladder the mucous membrane of the vagina was incised around the neck of the organ of gestation, and detached from it up to the peritoneum which was cut transversely. It only remained now for the two ligaments to be cut across and tied, and the uterus was taken out. The after treatment was simple, the wound was sutured, a drainage tube was placed under the peritoneum, and the vagina filled with gauze impregnated with iodoform, the drainage was withdrawn on the fourth day, and by the twenty-second the patient was well. M. Ferrier said he had practised the same operation in a woman, *æt.* 47, and the patient got well.

**DOUBLE CASTRATION.**—M. Terrillon reported a case of double castration which occurred in his practice for a fibrous tumour accompanied by excessive pain, the patient got perfectly well. In another case he was not so fortunate, the motive of the operation was abundant recurring hæmorrhage. The patient died a month afterwards from phlebitis. M. Ferrier said he had done the operation himself twice with good results in both cases.

**NEW ANTISEPTIC DRESSING.**—M. Championnière showed the Society a new method of antiseptic dressing which he considers superior to any other, *viz.*, wadding or *charpie*, rendered antiseptic by corrosive sublimate, at the same time he powders the lines of suture with mixture of iodoform, benzoin, carbonate of magnesia, and eucalyptus.

WEDNESDAY, JULY 29, 1885.

### THE DIAGNOSTIC VALUE OF DELIRIUM.

WE have so often expressed our admiration for the priceless treasures of scholarship and knowledge contained in the pages of the ever-welcome *Asclepiad* that there remain to us nothing stronger than familiar terms of praise with which to receive each new gem of thought or practice that comes to us in quick succession from the busy pen and active mind of its accomplished author. Rich in suggestion, however, as are all the articles which Dr. B. W. Richardson has generously offered as a gift to the profession, there is hardly one which is more deserving of a wide reception at the hands of reflecting and observant practitioners than that which appears in the current issue of the *Asclepiad* under the title of "The Mind as a Diagnostic Surface." In this essay Dr. Richardson further develops an idea, formulated in an earlier number of the same serial, to the effect that special regions of the body, when overcome by disease, react in a special and distinctive fashion on the mind, with the result that a particular kind of delirium is excited from the characters of which it is possible to frame an accurate diagnosis respecting the part of the body affected. In this way there are at present recognised and described by Dr. Richardson four forms of delirium, which he terms respectively *Delirium Inquietans*, *D. Desperans*, *D. Dubitans*, and *D. Sperans*. The unquiet form of

delirium is seen most frequently in association with diseases of the heart, and is very graphically described by Dr. Clifford Allbutt in this connection. "The subjects of it are," he writes, "often very unmanageable. But the common character of it is a *delirium of place*: the patient longs to be allowed to go home, or he insists on rising from bed, dressing and going away by rail; or he is incessantly posted about in a carriage or coach; or he is in some new bedroom, house, or inn, and begs to be restored to his own chamber. I have now watched this delirium so often that I may say that such delirium, though by no means confined strictly to chronic heart disease, is most characteristic of it."

Clinical experience readily lends support to the conclusion that is here drawn; and it is conceivable that a most valuable aid is offered in these observations to many who would, without the suggestion they contain, fail to be influenced sufficiently by signs which, however obvious to the sight, carry no information until their explanation has been afforded. Concerning this part of the subject, Dr. Richardson comments most instructively on that form of delirium to which he has applied the qualifying term "*desperans*," and which is found in association with disease of the lower bowel, whether cancerous, hæmorrhoidal, or other origin.

"The one characteristic of it is depression, gloom, coupled sometimes with acerbity, reaching to actual dislike of any person, or act, or thing which gives real or imaginary offence. In most instances the delirium extends to despair, with a recklessness as to life, but without suicidal proclivities, and even a desire to die rather than live, unless relief can be obtained." Further on we learn that, according to the writer's observation, "cancer causes *delirium desperans* or not, according to the part of the body that is invaded by it. When it attacks the lower portion of the alimentary canal, it causes extreme dependency, but so would other diseases in the same part. The variation which is displayed is from a direct or a reflex influence emanating from the affected part and extending to the mental surface."

It is, of course, not to be expected that ready and satisfactory reasons can at once be found for every phenomenon to which attention is directed in the study of the clinical features of disease; and we would suggest in this connection that a weightier influence should be assigned to the sympathetic nerve system, and its power of modifying and determining the incidence of reflexes, in further considering the data which Dr. Richardson has supplied. We know to what a profound extent the phenomena of disease are dependent on the capacity of the sympathetic ganglia to arrest, to alter, and even to initiate peripheral changes; and it is a legitimate speculation that the various great centres of this description within the body may be even endowed with qualities which are none the less real because of our inability to demonstrate them with existing means of illustration. And through such centres severally the mind itself may be influenced to the exhibition of emotions varying as widely as their exciting causes; but also invariable for the particular mechanism which is the intermediary link between cause and effect—in other words, the particular sympathetic segment involved.

But this is not the place to enter into theoretical exposition. Our object is rather to claim a well-merited attention to the invaluable remarks which Dr. Richardson has published on the subject, and to express a grateful feeling of admiration for the continued evidences he affords of the living interest maintained in the advance of a science which is already heavily indebted to him in ways innumerable.

#### THE RELEASE OF DR. BRADLEY, OF BRIMINGTON.

SIR RICHARD CROSS has earned the thanks of all lovers of justice and fair play by having taken the trouble to inquire into the circumstances of Dr. Bradley's conviction and sentence, and Sir William Harcourt has incurred an equal amount of discredit for having allowed an innocent man to languish in prison because he could not shake himself clear of the fetters of red tape, and apparently cared very little about such small matters as the ruin and incarceration of a doctor. We have no hesitation in making such a charge against the late Home Secretary, because we knew enough of the evidence in the case to be quite certain that any one who studied it must pronounce Dr. Bradley innocent, and because we have reason to know that Sir William Harcourt, all through, was entirely ignorant of the facts, and set at naught every appeal to him to make himself acquainted with them. He had actually in his portfolio the official report of the medical jurist who investigated the case on behalf of Government, declaring that Dr. Bradley had been convicted on utterly insufficient evidence, and we believe that that report, if read at all, was never duly considered, and no effect was given to it.

We offer to the memorialists in Chesterfield, Nottingham, Sheffield, and elsewhere, who pressed home their protests, our warmest congratulations on the result, and we regard with much self-satisfaction the fact that the *Medical Press and Circular* was the first medical journal which took up the subject, which worked it with any enthusiasm, or which persevered in the face of the refusal of Sir William Harcourt to hear our importunities. Those who, apparently, did not care a straw for Dr. Bradley are now effusive in their glorifications, and we are now told that "the Council of the British Medical Association," which never responded in the least to appeals for help when help was needed, "is now afforded an occasion for a full consideration of the circumstances and of the steps which the Council may think it right to take in this distressing case," for which modicum of interest in Dr. Bradley, we have no doubt that he and the medical profession in the Midlands will be truly grateful.

We have, however, no intention of dropping the case, and we hope the memorialists will not do so until Dr. Bradley's good name is finally and publicly re-established and public *amende* made to him for the great injury done him by the breakdown of our legal system. Sir Richard Cross has said that Dr. Bradley is not guilty enough to deserve punishment, but, to avoid granting compensation, he has, most improperly, coupled that declaration with the statement he is not sure that innocence has been

proved. We assert that Dr. Bradley's innocence has been legally proved by the absence of any tangible proofs, and we say that that innocence is established in the minds of all who have read the evidence, and we, therefore, demand that his exculpation shall go the full length of acquittal and compensation. No half-vindication or so-called "pardon" will satisfy any one. If he be guilty even in a minor degree the profession does not desire to see him liberated, and repudiates his cause, but if he be innocent the authorities who dictated a verdict of conviction, imposed a sentence of bitter severity, and refused to hear a word of remonstrance, must, in justice to this innocent man, declare his guiltlessness.

#### DISQUALIFICATION BY MEDICAL RELIEF.

THE question as to whether a pauper in the matter of medical advice and a recipient of medicines on charity shall be endowed with the selection of our law-makers, having been transferred from the arena of medical politics now it is perhaps useless to discuss it from the point of view of either the doctor or the Poor-law economist. The opponents of the newly-extended franchise argue against the Disqualification Bill, quoting the arguments which every medical politician has used against the unlimited extension of charity relief to well-to-do people; but the House of Commons has long since put these considerations aside, and has given its decision that, no matter what the disadvantages may be or what violations of principle may be involved, the pauper ought to be, not only privileged, but entitled to vote, and that all politico-economic traditions ought to be sacrificed for the purpose of creating him a ruler of the destinies of the nation.

Nothing can more forcibly illustrate the complete subordination of all such considerations than the conduct of the Government with reference to this Bill, for they have, almost unasked and without the least scruple, put aside by their own Bill the whole of the principles which, a few weeks ago they told us were absolutely inviolable, and have, with the utmost serenity, advocated a change of system which two short months since they declared would be ruinous to the taxpayer, destructive of the independence of the voter, and subversive of all the legitimate principles of self-government; and, having in view these evidences of the compressibility of the new Government, Mr. Jesse Collings and his Radical supporters have naturally seen their way to demand fresh privileges for their *protégé* the pauper voter. The amendment upon which they have defeated the Government is as follows:—"The term 'medical or surgical assistance' in this Act shall include all medical and surgical attendance, and all matters and things supplied by or on the recommendation of the medical officer having authority to give such attendance and recommendation at the expense of any poor rate." This party insist that not only shall the voter exercise a political influence similar to that exercised by the taxpayer by whose charity he receives doctoring and doctor's "stuff," but that that influence shall not be diminished even if he sponges on the taxpayer for food, drink, clothes, or carriage exercise, or, in fact, for anything which the taxpayer buys, but which the pauper may obtain for nothing through the doctor's agency. If Mr. Jesse Col-

lings has his way—as seems likely—it will be quite possible that the pauper may not only invoke the parish doctor's aid, demand medicines, and trusses, and other mechanical appliances, be granted beef-tea, eggs, and wine at the cost of the taxpayer, but actually be conveyed to the poll in a carriage hired on the doctor's suggestion, if he be prevented by his disease from walking there without detriment; and when by these means he presents himself at the ballot-box, he will be recognised as great a power in the State as the victim at whose expense he has enjoyed all these privileges.

We have already pointed out that, inasmuch as the chief barrier against wholesale imposition upon the taxpayer is thus levelled, the financial effects of wholesale pauperism upon the public and upon the doctor must be looked for. Mr. Jesse Collings and the Radicals, undeterred by a serious semblance of protest on the part of the Conservative Government, will, within the next fortnight, transfer to the pauper list many tens of thousands of small artisans, cottagers, and others who, as long as they sacrificed their votes by accepting the transfer, refused to appear on that list, and the party will have achieved its object of adding to the voting-lists a large number of working-class voters who have, heretofore, not cared enough for the franchise to induce them to pay the doctor. But the effect on the profession is obvious. So far as the parish doctor's pauper constituency is increased, so far must his cheap-fee constituency be diminished, and so far must the provident dispensary doctor and the prescribing chemist suffer in pocket. And whatever amount of private income is thus subtracted from the parish doctor must, in the long run, be necessarily made up to him by the taxpayer in his official emoluments.

Mr. Jesse Collings and his party will, no doubt, say that this is as it should be; that it is very good work for the taxpaying capitalist to pay the pauper voter for exercising his suffrage; but neither a medical journalist nor a political economist can be expected to endorse that view. It is, no doubt, the duty of the community to provide the indispensable medical help for those who cannot by any means obtain it for themselves; it may even be right in principle and wise in practice to give to persons who contribute nothing to the public welfare, but rather burthen those who do so contribute, all the privileges of citizenship which other people pay for; but it seems to us that it can hardly be wise for the community to go out of its way to give the same advantages to persons who are quite capable of paying for them, but will not do so as long as they can avoid it, and to allure such persons to become paupers by promising them for nothing medical luxuries in addition to medical necessities.

### Notes on Current Topics.

#### Fæcal Fistula after Ovariectomy.

THE perfection of skill with which the modern operation of ovariectomy is almost invariably performed, must be accepted as the explanation why it is so rare to have it followed by such distressing accidents as fistula, &c., which would necessarily result from rough or improper handling of the parts. Accounts of complications of the

nature in question are, however, still occasionally to hand, and our American exchanges report a case of fæcal fistula occurring after ovariectomy, and read before the Ohio State Medical Society by Dr. C. D. Palmer. The patient was a delicate unmarried woman, twenty-two years old, and the tumour had existed forty-two months, having been tapped eight times under the impression that it was ascitic. Twelve days after ovariectomy was performed a fæcal fistula developed; it communicated inwardly with the lower small intestine, the external opening presenting midway between the umbilicus and the symphysis pubis. At first there was a daily discharge of fæcal matter to the amount of several ounces, but it diminished gradually under the influence of firm pressure, and at the end of three months the amount varies from one to three drachms per day, with the continuance of steady improvement.

#### The Intercollegiate Doctorate.

FOR some time past, as announced in these columns, a joint committee of Fellows of the Royal Colleges in London has had under consideration the question of obtaining powers by which the Colleges will be enabled to confer on those who obtain the licences of both institutions the title of "Dr." It is now generally understood that this committee is agreed as to the justice and necessity of such a step, and that it is prepared to suggest a means by which the innovation may be rendered practicable. The matter will come up for discussion in all probability at the meetings to be held at the Colleges to-morrow (Thursday), and some definite undertaking in connection with it is likely to be witnessed soon. We have in previous articles so clearly shown the grounds on which we think that this step is one to be desired, that we need not now renew the arguments that can be employed to this end. It is enough to point out that the student whose curriculum is pursued in London, and whose examinations are passed at the Colleges of Physicians and Surgeons of England, undergoes both a training in medicine and surgery, and a test as to fitness for practice that are unequalled in any centre of qualification out of the metropolis. Moreover, he complies with precisely the same conditions as are fulfilled by the University student at, say, Edinburgh, Aberdeen, or Durham, save only that his fees are heavier, and his expenses greater, in that he lives in a London lodging instead of in a provincial one; and these facts being so, it is an unmerited wrong that deprives him of the advantages conferred by the right to call himself Dr., a right, moreover which is purchased at a much less cost by men who consent to forego the privileges of clinical teaching in London in order to gain the fee-compelling title. It is sheer nonsense to claim superiority in the matter of education for the M.B. of any of the places named, over the L.R.C.P. Lond. and M.R.C.S. Eng., and it is satisfactory to find that this is now generally admitted. Oxford and Dublin alone of the Universities now retain for their medical graduates the special mark of scholarship conferred by a compulsory arts degree; and in these circumstances the Universities which have reduced themselves to be mere competitors with the corporations as licensing bodies must be deprived of their pretended superiority, by giving to the colleges an equivalent power

to that they possess as far as the title of "Dr." is concerned.

#### Hospital Sunday Fund.

THE collections made on behalf of the Hospital Sunday Fund this year show signs of the existing depression in their smaller amounts as compared with those of 1884. Some anxiety has naturally been excited in this connection, and especially since several of the more important charities have been so frequently driven to utilise their invested capital that the certain income they enjoyed is reduced, in some cases, almost to *nil*. Under these circumstances an attempt is to be made to raise the total amount of this year's collection to £40,000 before the 31st of July, on which date the distribution commences; and to this end Dr. James Wakley has contributed £1,000 to the fund, in the hope that some of the wealthy traders that gain their money in London will unite to make up the deficit of £7,500.

#### Death of General Grant.

THE long and painful illness so heroically borne by one of the greatest soldiers of modern times terminated on Thursday last, when General Grant died surrounded by his family, and to the universal regret of the whole civilised world. To the profession of medicine his illness and death possess an interest over and beyond what is compelled by the circumstances surrounding the life of the great American hero, for we are even now in doubt as to the actual disease to which his death at the comparatively early age of 63 is attributable. The marvellous alterations in the condition of the illustrious patient which have been chronicled during the last few months, cast a doubt upon the first definite diagnosis of the illness as cancer involving the throat. Unfortunately, too, the relatives of the deceased general have felt it their duty to decline permission for a post-mortem examination of the body, so that the only satisfactory method of determining the actual nature of the growth, that, namely, of direct microscopical investigation, has not been possible. That the disease was one which kills by progressive exhaustion is clearly evident from the history of the case; and no one can fail to admire the noble fortitude with which the invalid bore up and successfully concealed from the dear ones around him the real extent of the suffering he endured. The picture submitted to us is indeed one of the most wonderful conquests over pain, and it is sad to think that he whom it depicts, capable still of much world-benefiting labour, should have fallen a victim to a disease before which medicine is powerless and art unavailing.

#### The International Congress.

LATEST advices from America do not represent any very great improvement in the circumstances surrounding the squabble between the various committees by which the arrangements for the International Medical Congress of 1887 have been undertaken. There is something very ludicrous in the attitude of the committee appointed by the American Medical Association, and which on its own authority alone, presumed to undo the work already accomplished by the committee specially appointed by the

Congress at Copenhagen. The former self-constituted body has deposed the well-known and respected physicians elected by the later to preside in the various sections, many of whose names are of world-wide renown, and replaced them by a long string of nonentities, scarcely one of whom has ever been heard of outside the village in which he gains a living. The few celebrated physicians who were graciously permitted to retain official posts have naturally and properly shown their disgust by declining to be associated with the strangely mixed representatives of American medical science who are elevated into notoriety by the action of the Association ring; and things are now at such a pass that even the home journals are reckoning up the meeting as certain to be a miserable failure. The more sensible organs, however, are tendering the malcontents a piece of advice which they will do well to act upon, namely, that at their next meeting they should quietly determine their official existence, and resign the organisation of the conference to men of standing in the profession, and who will be able to command confidence and respect on this side the Atlantic. Unless some definite action of this kind is speedily taken it is a moral certainty that the Congress, if persisted in, will lose every atom of its international character; for no one is going to contribute papers, or be at the expense of reading them to an assembly of mutual admirationists whose meddlesome conceit is scarcely equalled by their obscurity in the world of medicine. We have still, however, sufficient faith in the good sense of our American *confrères* as a whole, to feel assured that the little band of nobodies will speedily be sent to the rightabout, and the direction of the arrangements reassumed by the men who ought never to have resigned the trust reposed in them.

#### Fees on Dispensary Tickets in Ireland.

IN the case of *Palmer v. Bailey*, heard before Judge Lawson on appeal at the last Monaghan Assizes, a judgment was given which seems to have an important effect upon the position of dispensary doctors in Ireland. Dr. Benjamin Palmer was the appellant in the case referred to, and the respondent was a respectable farmer residing in county Monaghan, within Dr. Palmer's dispensary district. Having received a red ticket, signed by the relieving officer, the doctor attended on two occasions the respondent, and having ascertained that another medical gentleman, who of course was retained, was in attendance, he brought the matter before the dispensary committee which first sat after his receiving the ticket, and upon the facts stated by one of the committee the ticket was cancelled. Dr. Palmer therefore instructed his solicitor to bring a civil bill action, which was dismissed in the County Court. He appealed to the going Judge Assize, and on the hearing there was no denial of the respondent's ability to pay, and it was further admitted that the red ticket had been properly cancelled. Between the counsel at the bar it was arranged that the sole question for the judge to try was whether, having regard to the fact that the doctor had received a red ticket, he could recover for his attendances. The Judge without a moment's hesitation ruled that he could not, as there was no promise to pay either expressed or implied. The case of *Delahoyde v. Wilson*, in which the

plaintiff recovered his fees before the Recorder of Dublin, was cited, but of course it was not binding, as it was a decision of an inferior court.

This judgment is, so far as it goes, very discouraging; but too much value ought not to be attached to it, and it certainly should stimulate the Irish Medical Association to reopen the question at the first opportunity. Cases of this sort, dealing with technical law, are almost always mismanaged at Assizes, and the decisions arrived at are hasty, and dictated rather by rule of thumb and first impressions than by careful interpretation of the law. This is not wonderful, considering that provincial solicitors have little special acquaintance with medical law—that these cases usually come up for hearing amongst a crowd of land cases and other questions of daily occurrence—that the counsel employed are generally not instructed in time to make up their points, and that the Judge is usually in the same condition, and cannot take time to look up the law of the case, because he must get through his work and move on to the next town in his circuit.

If Judge Lawson be right in this case, numerous other judges of lower courts and numerous legal advisers of high repute must have been all wrong. In any case, our information on the exact terms of the judgment and the arguments adduced is meagre, and we shall try to obtain further details.

#### The Political Influence of the British Medical Association.

DR. JACOB gives notice that, upon the consideration of the Report of the Parliamentary Bills Committee, he will move—"That it be an instruction to the Parliamentary Bills Committee, in view of the approaching general election, to take immediate and active steps to organise the political power of the Association; to ascertain definitely the views of parliamentary candidates upon those questions in which the Association and the medical profession are specially interested; and, so far as may be possible, to influence the members of the Association to give their votes for those candidates whose views, so ascertained, are consistent with the policy of the Association and the good of the profession."

#### Universities' Bill (Scotland).

It is evident that the forces of the objectors to the Universities' Bill (Scotland) are gathering. Within the last week a number of fresh notices of opposition have been tabled. As we hinted some weeks ago, the main contest will be waged over the subject of University administration, the enemies of the Bill demanding sweeping changes in the University Court. Without entering again on the discussion of this important subject, we are inclined to think that a sense of coming danger on this score is at the bottom of the freshly developed zeal on the part of some of the more pronounced friends of the measure. On Friday evening last Sir Richard Cross was waited on by a deputation from the Universities of Edinburgh and St. Andrews in favour of the Bill. Sir William Muir, Professor Masson, and Professor Laurie represented Edinburgh, and Principal Tulloch and Professor Knight, St. Andrews.

They were accompanied by Sir Lyon Playfair, Mr. J. A. Campbell, and Mr. Williamson. The line apparently taken up by the deputation was that the alterations required were so slight as practically to make the measure a non-contentious one. Perhaps in the Home Secretary's gentle reference to time as the greatest difficulty in the way of the Government's pushing on with the Bill there was just dropped the gentlest hint possible that it might not be such perfectly smooth sailing as the sanguine deputies imagined. We fear much that another session will be needed ere an amended Universities' Bill becomes law.

#### Dr. Elmes, of Limerick.

WE learn with great satisfaction that the notice of the death of this estimable gentleman which appeared in our last issue is erroneous. Though Dr. Elmes has been dangerously ill, he is now much better, and is making a rapid recovery. The announcement of his death was made by us on the authority of a Limerick newspaper published at Dr. Elmes's door, and therefore presumed by us to be a safe source of information. We are naturally much distressed at having made such a mistake.

#### The Meeting of the British Association for the Advancement of Science.

THE hon. local secretaries of the British Association have issued a circular of invitation to the meeting to be held in Aberdeen during the early part of September, under the presidency of Sir Lyon Playfair. Twenty-six years have now elapsed since the Association last met in that city. The Pharmaceutical Conference will also be held at Aberdeen. All the railway companies issue cheap tourists' tickets to Aberdeen, available until the end of December. The railway communication between Aberdeen and the Northern Counties by the Highland Railway, the Caledonian Canal and the Dingwall and Strome Ferry route will enable visitors to see many other places of interest. The city of Aberdeen itself abounds with excellent hotels and lodging-houses, a list of which can be obtained on application to the local secretaries of the British Association, and there is every reason to expect the meeting will be no less successful than it was on the last occasion, when the late Prince Consort occupied the position of President. The neighbourhood presents numerous objects of interest, not only of modern date, but also others to attract the antiquarian and geologist. At the present time Aberdeen occupies an area of more than ten square miles, and the population is upwards of a hundred thousand. It abounds in fine buildings, ancient and modern, among which may be mentioned the Town Hall, finished in 1873, with its great tower two hundred feet high, from which a fine bird's-eye view of the city can be had by those who take the pains to climb to the balcony. Among the older buildings the Trades Hall, Marischal College, King's College, and the Cathedral St. Machar, are in various way of especial interest. The Old Market Cross in Castle Street, of which the Aberdonians are very proud, is a unique specimen of this kind of structure, and the old "Brig o' Balgownie" is so celebrated that no one

visiting Aberdeen will readily fail to see it. The country round Aberdeen is rich in places of historic interest, especially along the banks of the Dee, where those who have time can well spend a few days or longer after the business of the meeting is over.

### The Conway Guardians and their Medical Officer.

WE understand that Mr. Davies's case is likely to come before Parliament this week. It will be remembered that this gentleman, who since 1873 has been acting as district medical officer of the Conway Union at a salary of £75, with the usual extras sanctioned by the Local Government Board, has been the object lately of unprovoked insults because the expenses on "extras" have increased with the population beyond what the guardians, in their limited vision, consider they should, and to reduce which they have striven unsuccessfully to compel Mr. Davies to commute his extra fees and the cost of drugs to £10 per annum. As he firmly refuses the proposition, rightly regarding its acceptance as a stigma on his character and an insidious attempt to compel the employment of inferior and inexpensive drugs, the guardians have resorted to the expedient of threatening to stop his salary. Meanwhile, a deadlock has resulted, Mr. Davies has ceased to order expensive medicines, as the guardians refuse to pay for them, and they are endeavouring to make his position—as they have no legal power to oust him—as uncomfortable as possible, with a view to his resignation. We would reiterate our counsel previously given, that Mr. Davies stand firm, as have others similarly placed, discharging his duties to the poor and calmly awaiting events.

### Tentes Abri.

AN enterprising Frenchman has submitted to the War Office a proposal to supply, for the use of the soldiers of our army, a description of shelter tent invented by himself, as he says, "after many trials extending over a long term of years," and he submits the further proposal that he should supply "patterns of his tents to the British War Department, and concede to Her Britannic Majesty's Government the sole right in British territory of making and using them in consideration of the following conditions," one of which is that a payment be made to him "of pounds British sterling forty thousand (£40,000)." The tent proposed to be thus "given away" to perfidious Albion for "a mere song" is described by its inventor somewhat after this manner:—It should be water-tight, divisible into four pieces, each piece to be carried by a separate man, to enable "any four men meeting each other to pitch a tent. Instead of a centre pole, one or more rifles are to be utilised to support it; instead of corner pegs, the short spade each man in most armies is now provided with should be used." On the actual march "each quarter tent can be rolled inside a soldier's blanket, and this again in a piece of painted canvas or waterproof cloth 6 ft. 6 in. long by 2 ft. 6 in. broad, which is used for sleeping on," the whole forming "a handy parcel which can be conveniently strapped on the knapsack." The next proposal made is that in order

to compensate for the extra weight thus inflicted on the soldier, extra boots, trousers, &c., should be carried in the baggage train, and supplied to the men concerned before the old articles are worn out.

Let us briefly consider the particulars above presented, and endeavour to picture a regiment of British infantry on active service—say, in the Soudan—and equipped after the manner indicated; let us further picture to ourselves the Arab forces hovering at a distance, waiting for the fitting moment in which to deliver their attack. Weary, and with his already heavy knapsack, overburdened with his portion of the *tente abri*, the British soldier reaches the zareba in which he is to rest for the next few hours, and there recruit his physical powers before resuming his onward progress in the face of his agile and watchful foe. "Each man in parties of four produces his quarter tent, and fastens it to those of his three comrades. The top is secured by suitable means provided, and the whole tent laid on the ground. The corners are hauled out to their proper position and made fast to the handles of short spades (or, failing these, to tent pegs), which are stuck in the ground. The top is then lifted, and one or more rifles placed underneath to act as a centre pole." Into the tents so constructed the greater number of the men retire to temporarily rest, their arms converted, not into pruning hooks, but into tent poles; their intrenching tools into pegs. The Arabs seize their opportunity, there is a wild cry, they rush in thick masses upon troops exhausted from overburthens on their desert march under the fierce sun, half deprived of their weapons and other means of defence, and entangled in their *tentes abri*. Under such circumstances one result, and one only, need be looked for. As a matter of fact, there are many officers of experience, even in the French army, who condemn these shelter tents as being worse than useless, as being an encumbrance and a nuisance to a force in active operations against an enemy.

### The Social Science Association.

WE understand that, in consequence of the general Parliamentary election occurring during the autumn, the Council of the Social Science Association has decided not to hold the customary congress this year. It is, we believe, the first time in the history of the Association that an annual gathering has not been held, and many enthusiastic supporters, men of scientific proclivities, will doubtless regret the break in the long roll of annual successes now rendered inevitable. Expressing as we do the opinion of the general body of members, we fail to see that this organisation is so inseparably interwoven with politics that an election should be allowed to interfere with meetings whose objects are confined to the reading and discussion of papers on social science. True some of its officers, notably the President, the Right Hon. G. Shaw-Lefevre, will be contemplating and watching with interested eyes the effect of enfranchisement on expanded constituencies; but these are few in number, and even so far, the annual gathering would be some weeks over before the general election takes place. But it is now too late to insist on the point; an unfortunate precedent has been established, and Bath, which had

been provisionally decided on, is doomed to disappointment.

### The English Conjoint Scheme Board.

SOME idea of the influence which will be exerted in the future over preliminary medical education by the combined English colleges will be gathered from the fact that at the primary examination now in progress more than five hundred candidates have presented themselves. So great is the pressure put upon the resources of the Colleges that in addition to the accommodation offered by both these institutions, arrangements have had to be made for the use of the Westminster Town Hall as an examination room for the written test. It should be remembered, however, in connection with this rush of students, that a good many are likely to seek to pass the first examination under the conjoint scheme with a view to escaping a similar test elsewhere. Many, too, are probably unregistered students, to whom the privilege of entering for this examination prior to commencement of hospital studies is conceded, and, lastly, this period is the end of the first academical year under the new regulations of the combined Examining Board in England.

### The Conjoint Examination Scheme for Ireland.

FOR the fourth time within the last twelve years the negotiations for establishing a conjoint examination by the Colleges of Physicians and Surgeons in Ireland has completely broken down, and it is to be hoped that we have heard the last of these attempts to cobble up a system which will not bear mending. We informed our readers about three months since that the Council of the College of Surgeons had again resolved to make approaches to the College of Physicians, and had appointed a special committee to work out the negotiations. That committee submitted to the College of Physicians a scheme which provided—*a.* That the three primary examinations of the student should be by the two Colleges conjointly, and the final examinations separately; *b.* That there should be a considerable reduction in the existing diploma fees; and *c.* That the surplus remaining after payment of examiners' fees should be divided in the proportion of 5-8ths to the College of Surgeons and 3-8ths to the College of Physicians. This apportionment of the money had been agreed to by the Colleges in every one of the preceding schemes, but on this occasion the College of Physicians has taken higher ground, and has refused to accept any less share than half the money, and has thereupon sent back the scheme to be again reported on *sine die*.

We have already so strongly condemned these private conjunctions of Colleges as mere expedients to stave off a comprehensive and much-needed reform that it will be easily understood that we are gratified by the collapse of the present negotiation. What benefit was to be gained from it we have never been able to ascertain from its most ardent advocates; but the disadvantages were manifest to all, and it is very satisfactory that, in their scare against reform, these conjoint schemers have not succeeded in damaging the Colleges as they proposed.

ON Saturday afternoon a new iron screw steam vessel, built for the Port Sanitary Committee of London by Messrs. Edwards and Symes, was successfully launched at their works, North Greenwich. The boat, which is 59 feet long, and 11 feet beam, is arranged to accommodate the medical officers and inspectors forward, and has a large cabin aft for the conveyance of sick persons to hospital. She was built from the designs of Dr. Collingridge, the medical officer of the Port, and Mr. A. D. Lewis, naval architect.

## Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

SCHOOL OF MEDICINE, EDINBURGH.—PETITION FOR A CHARTER.—A deputation from the Extra-Mural School of Medicine, consisting of Dr. Stevenson Macadam, Dr. Craig, Dr. James, and Mr. Malcolm McGregor, S.S.C., waited on the Lord Advocate on Friday, with the view of bringing under his lordship's notice their petition to the Privy Council for a Charter. They emphasised the fact that at present their rightful development was handicapped by their inability to take united action. Thus, as a result of their incorporate character, no bursaries or scholarships could be left to them, and, further, they were unable to do anything to rectify certain disadvantages under which their students laboured as compared with those attending the University. They suggested that the title of "Queen's College" might prove suitable, instancing Queen's College in Ireland, Queen's College in Birmingham, and others. The Lord Advocate promised to look into the matter, and take it up where his predecessor had left off. He was of opinion that there should be no suggestion of jealousy between the Extra- and Intra-Mural Schools of Medicine.

DR. THOMAS KEITH, OF EDINBURGH.—We understand that Dr. Thomas Keith has just returned to Edinburgh from America, after a three weeks' absence, whither he had been called on professional duty. This is, we understand, the only time that surgical assistance has been asked from the old world to the new; and that it should have been so asked is a high compliment to Dr. Keith, who is undoubtedly the foremost ovariologist, as it is also significant homage to the fame of the Edinburgh Medical School (Extra-Mural!).

EDINBURGH.—HEALTH OF THE CITY.—For the week ending with Saturday, the 18th inst., the mortality in Edinburgh was 61, and the death-rate 13 per 1,000. There were 10 deaths under 1 year, and 10 above 60, of which 1 was above 80, and 1 above 90 years. Diseases of the chest accounted for at least 40 deaths, and zymotic causes for 6, of which 1 was due to diphtheria, 3 to measles, and 2 to whooping-cough. The intimations for the week comprised—Fever 5, diphtheria 2, scarlatina 21, and measles 25.

EDINBURGH UNIVERSITY.—CLOSE OF THE SUMMER SESSION.—Last Friday the summer session at Edinburgh University, which commenced on the 4th May, was brought to a close. The final and second professional lists are now completed, and the graduation ceremonial takes place on the 1st August. It is understood that the theses for M.D. this year are of peculiar merit. The task of adjudicating honours is considerably increased by this *embarras de richesse*. The winter session is advertised to open on the 27th October.

EDINBURGH UNIVERSITY.—GUNNING SCHOLARSHIPS.—The three Gunning Scholarships which were competed for

on Saturday, 18th July, have been awarded as follows:—Fellowship tenable for two years—James Edwards, M.A. (£100 per annum). Scholarships tenable for two years—John Stenhouse (£40 per annum); W. A. Reid (£30 per annum); Alex. Whyte, M.A., B.Sc. (£20 per annum).

PRESENTATION TO DR. COSSAR EWART.—On Thursday last, the 23rd inst., Professor J. Cossar Ewart, of the Chair of Natural History in the University of Edinburgh, was presented with a gift by the students, in view of his approaching marriage. The testimonial consisted of two massive lamps raised on silver Corinthian pillars, of beautiful design and workmanship. Count Alexis Bobrinsky made the presentation on behalf of the students, begging him to accept with it the expression of their most sincere and hearty congratulations upon his approaching marriage. Professor Ewart thanked them heartily for their handsome present and kindly words, which he hoped in the future to more fully merit.

### Correspondence.

#### DR. BRADLEY'S CASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I trust the sympathy felt by the members of the profession towards our unfortunate *compère*, Dr. Bradley, may show itself in a practical form—Firstly, By securing his restoration to the Medical Register; secondly, by furnishing him with the means of making a fresh start in life abroad, as he is scarcely likely to remain at home after the treatment he has received. If you, in conjunction with the editors of the other medical journals, will undertake to receive subscriptions, please put my name down for £1 1s. It is a pity Sir R. Cross could not have gone farther, and done more complete justice to Dr. Bradley; but it is perhaps more than we could expect. The Home Secretary's position was one of extreme delicacy and difficulty. He was bound to show some consideration for his predecessor's feelings. As for the latter (Sir William Harcourt) the members of the medical profession may well bear in lively remembrance the contemptuous indifference with which he treated their opinion, which was expressed with a most marked unanimity, and in language the strongest which it was possible to use, when the day comes that will bring him and his party face to face with the electoral opinion of the country. Justice should be beyond the suspicion of being influenced by the spirit of party friendship. Such has not been the case in this instance. The judge by whom it was tried is known to be a strong anti-vivisectionist, and, rightly or wrongly, is suspected of being anything but a warm friend to medical men. When there was a failure to convict upon the major count, he was certainly the means of securing an adverse verdict on the minor one. In passing sentence, he passed one that was nothing short of being vindictive. He is known to be a strong partisan. Instead of looking into the evidence of the alleged crime himself with the aid of the law officers of the Crown, and giving due weight to the expressed opinions of a thoroughly representative and influential body of the medical profession, who may fairly claim to speak as experts in such cases, and against whose opinion, had it been expressed in court, it would have been impossible for any jury to have convicted, the late Home Secretary was content to refer the consideration of the case to the judge himself whose justice was on trial, and, be the influence or cause what it may, was satisfied to cast a slur upon members of a profession as high-minded, honourable, intelligent, and as anxious in the cause of morality as either members of the bench or members of the bar are or can be, preferring to take the *ipse dixit* of one whose dignity was at stake, and who had a decided interest in maintaining a conviction which he had done so much to secure. The conduct of both judge and Home Secretary has aroused in the minds of medical men feelings of the bitterest contempt for their purity of motive and conduct, and nothing will ever remove from the minds of members of our profession the conviction that in Dr. Bradley's case there was a gross miscarriage of justice, and that the unfortunate man was

sacrificed to private antipathies against a profession as a whole, and to party friendships. The relations of a medical man towards his patients are such that it is impossible for them to escape exposure to dangers such as those which Dr. Bradley has encountered, however circumspect and prudent they may be; and nothing short of the clearest possible evidence of guilt should suffice to secure a conviction.

Verdicts sustained by insufficient, or, as in this case, incredible evidence, would soon render it impossible for medical men to do their duty towards their patients at all, since they would be at the mercy of any hysterical, epileptic, or designing woman who might take into her head to bring such charges against them.

I trust the profession will, by opening their purses, show to Lord Coleridge and Sir V. Harcourt their opinion of the manner in which they have acted, and make some atonement to Dr. Bradley for the ruin which was so lightly and unjustly brought upon him. Sheffield medical men do not feel highly honoured by the scant courtesy they have received at their hands, and are pretty likely to remember it.

In conclusion, I would strongly urge the formation of an association amongst medical men for defence purposes under similar circumstances. Medical men who were in court when this case was tried were convinced that had the evidence been properly presented to the jury, and had expert evidence been called, a conviction would have been impossible. Medical men are not, as a rule, so blessed with an abundance of cash as to be able to secure the best counsel and proper evidence. Combination would easily effect this, and, for the safety of all medical men, or for the honour of the profession, the sooner it is carried out the better.

We all owe a deep debt of gratitude to you for your able advocacy of Dr. Bradley's cause, which we are thankful to see has been attended by such fairly satisfactory results. I trust you will not rest satisfied here, but that you will take up the notion of a common defence fund, and carry it to a successful issue. A subscription of half a guinea a year would be ample, and the association would prove a strong check to trumped up charges against medical men. As for real culprits, be their position what it may, no sympathy would be felt for them. The profession as a whole would rejoice at their condemnation and punishment.

Hoping you may find room for this letter,

I remain, Sir,

Faithfully yours,

JOHN W. MARTIN.

76 Brunswick Street, Sheffield,  
July 22nd, 1885.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A few weeks since Sir R. Cross refused to listen to medical evidence which would have absolutely proved Dr. Bradley's innocence. When the case is brought before Parliament he at once surrenders, but, unfortunately for his own credit, in surrendering he casts a most unjust reflection upon the doctor's character.

The Session is rapidly drawing to a close, so I hope Dr. Bradley's many friends in the House of Commons will lose no time in pressing home upon the Government the question of compensation.

Yours very truly,

EWING WHITTLE, M.D., M.R.I.A.

Liverpool, July 25th, 1885.

#### LETTER OF THANKS FROM DR. BRADLEY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I gladly avail myself of this my earliest opportunity to heartily thank you, and by your kind permission, through the *Medical Press*, my many other true friends in need, for your laborious and persistent efforts to obtain my release from Leicester Prison, which have happily ended in success.

Believe me that words fail to express my gratitude for all the sympathy shown me during my imprisonment. It is needless for me to comment on the case further than to say that I am perfectly innocent, and I am much obliged to

those in authority for their great kindness in granting me a free pardon for a crime I did not commit.

I remain,

Yours ever sincerely,

DAVID BRADLEY.

Barrow Hill, Chesterfield.  
July 23rd, 1885.

### SEXUAL DEAFNESS AND DEFECTIVE SIGHT!

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I read Dr. Griffith's very remarkable letter in your last impression, which for all intelligent men it is surely totally superfluous to characterise, and I have read also the correspondence which called forth the letter in question. Would you allow me to say that it confirms an impression which I have long held? viz., that, given a man with sufficient *savoir faire*, an illogical mind, a speculum, and the theory of reflex action, and let him settle in a crowded community, the chances are 100 to 1 that he will soon, by reducing pathology and science within the very narrow focus of his intellectual capacity, attain to "no small practice and no small experience." For my part, I am lost in wonder at Dr. Griffith's statements, and fail completely to understand how any responsible medical man can give them expression, with the slightest hope that reason and common sense will homologate them.

I am, &c.,

D. CAMPBELL BLACK, M.D.

Glasgow, July 25th, 1885.

### BRIEF NOTES FROM OUR EXCHANGES.

#### DIAGNOSTIC VALUE OF THE FETAL HEART-BEATS.

DR. BOLZONI, of the University of Padua, finds (*Gazetta Med. Italiano*) as the result of his observations upon a carefully kept record of the foetal heart-beats in all cases admitted into the obstetric clinic for the scholastic year 1883-84, that the number of heart-beats is not in relation to the sex of the child, but is in constant and proportional relation to the weight, length, and biparietal diameter, i.e., to the mass of the body. The smaller number of heart-beats more frequently corresponds to the male sex, only because boys, as a rule, are heavier at birth than girls. The statistics concerning the foetal heart-beats, and the child's weight, go to prove his proposition, that "the number of heart-beats is a more constant guide to the development than to the sex of the child."

#### DIABETES.

Dr. Austin Flint, jun., treats cases of this disease with solution of arsenite of bromine (Clemen's) beginning with three and increasing to five drop doses, the patients being placed on a strictly anti-diabetic diet. He has lately added four more cases of diabetes so treated to the fifty-two already reported to the American Medical Association. Of these four cases three were permanently relieved. In his remarks Dr. Flint expresses his conviction that "diabetes has become to-day a disease easily and certainly curable, provided that the treatment be not begun to late."—*Cincinnati Lancet and Clinic*.

#### SALICYLATE OF ESERINE IN PHLYOTENULAR KERATITIS.

The following formula it recommended for use in the treatment of inflammation of the cornea of children:—

R. Salicylate eserine, gr. ij;  
Aqua, ʒss. M.

Sig.—One or two drops once a day to be dropt into the eye.—*The Western Medical Reporter*.

#### A PECULIAR EFFECT OF DIGITALIS UPON THE EYE SIGHT.

The case is related in the *Burgt der Rudolph Stiftung Vom Jahre*, 1883, of a man suffering from heart disease following rheumatism. The urine contained a small amount of albumen. The patient was placed upon three grains of digitalis leaves in the form of infusion per diem.

About a fortnight later he complained of weakened vision, as if a cloud were before his eyes. He could see better in the evening than by daylight. Had noticed the same occurrence when taking digitalis on a former occasion. No other symptoms of digitalis poisoning present, such as nausea, &c. Nothing abnormal noticeable about the eyes. Marked improvement followed the discontinuance of the drug for a few days.

#### FRacture OF THE BASE OF THE SKULL WITH LOSS OF BRAIN SUBSTANCE THROUGH THE EAR—RECOVERY.

A case of this accident is recorded in the *Philadelphia Medical News* last month by Dr. W. H. Wilder. The amount of brain-substance which escaped was about a drachm. The patient, a man, æt. 38, was admitted to the Cincinnati Hospital, November 30th. No history as to how the injury was caused could be obtained. When admitted, he was in a condition of drowsy stupor, from which it was hard to rouse him. Blood was flowing from the left ear. Respirations were full, numbering twenty per minute, temperature 99½° F., pulse 80. The pupils were active, and responded normally to the stimulus of light. No perceptible paralysis of the face existed. Towards the evening of the same day, the urine was passed in bed. On the 1st of December under the influence of an enema of castor oil and water, the bowels were freely evacuated. On the 2nd of December indications of facial paralysis of the left side was noticed. Pupils remained unaffected. Urine was drawn off by means of the catheter. No paralysis of the limbs existed. On the 3rd of December he commenced to improve and to regain sensibility. On the 6th December he was somewhat delirious, and had to be restrained, and put under the influence of chloral. On the 7th December, he had slept well, was much brighter, and from that date commenced steadily to improve, regaining his memory and intelligence. An examination of the ear on the 11th of December revealed the fact that the superior wall had been pushed downwards to such an extent as almost to close the canal. A fissure could be seen in the membrana tympani. The hearing of the affected ear was somewhat impaired on account of the acute otitis media that was present. Two months after leaving the hospital, the facial paralysis had disappeared with the exception of ptosis of the left eye; occasional pain was still felt in the left side of the face. Dr. Wilder was under the impression that only four such cases had been recorded with one recovery; in the discussion which followed the reading of his paper, however, other cases were mentioned by several speakers, and three other instances of recovery were noticed. For those interested in the subject, the paper, and the discussion are worth a reference.

### Literary Notes and Gossip.

THE transcribing and reproduction of Harvey's original M.S. lectures delivered before the Royal College of Physicians in 1616, containing the first suggestion of his discovery of the circulation, are proceeding uninterruptedly under the active supervision of Mr. Scott, of the British Museum, the facsimile work being entrusted to the Autotype Company. The cost to subscribers is fixed at two guineas, and the work is expected to be ready for delivery in the spring of next year.

MESSERS. CHURCHILL'S half-yearly list to hand affords presumptive evidence that efforts in medical literature during the past six months were the reverse of prolific, a fact which is certainly not to be deplored when the average estimate of recent work in this direction is considered. The fresh issues have been chiefly confined to new editions, and the new works are mostly graduation theses or college lectures and addresses republished in book form.

FROM the present month the weekly publication of the

German Imperial Health Office will be issued in an altered form. Hitherto, it has been principally devoted to vital statistics, but henceforth it will note all the new regulations relating to sanitary matters both domestic and foreign, cattle disease regulations, &c. The "Mittheilungen" that have become so celebrated will no longer appear, but in their place "Arbeiten des Ausden Kaiserlichen Gesund-Heitsamte" will be issued at irregular intervals. The publishers of both will be Julius Springer, Berlin. It is not expected that Professor Koch will commence his duties at the New Hygienic Institute before the Autumn session.

WE note that the *Midland Medical Miscellany* has changed its name this month to the *Provincial Medical Journal*, and with it its editor also. Ever since the inception of the *Miscellany* some three years since, it has been looked upon as a trade circular of its proprietors, Messrs. Richardson & Co., the well-known druggists of Leicester, but to give it a footing in London, a London editor was appointed last year. This, however, did not turn out a success, and a former member of the provincial staff of *The Medical Press*, Dr. Dolan, of Halifax, has now been appointed to take command. There is plenty of scope for a provincial medical journal; and we congratulate the proprietors on having secured so capable and energetic an editor as we know our former colleague to be.

MR. JAMES STARTIN, honorary surgeon and lecturer to St. John's Hospital for Skin Diseases, London, has published in pamphlet form the lecture "On a Healthy Skin" recently delivered by him before one of the London guilds. The author has wisely handled the subject from the preventive, rather than from the curative, point of view. The fact of the skin being one of the most important of organs is emphasised, and the rules given for the preservation of a healthy skin are essentially the maintenance in perfect activity of its function. Food and drinks must be carefully regulated, excessive and tight clothing avoided, the materials and colour of dress studied, while bathing and gentle friction of the skin is to be sedulously practised. Though addressed to the laity, the lecture contains practical hints which will repay its perusal by medical men.

MR. L. C. WOOLDRIDGE describes ("Proceedings of the Royal Society") the method of obtaining "a new constituent of the blood" which he has lately discovered, and dwells upon its physiological import. The plasma of the blood of a peptonised dog having been completely freed from all corpuscular elements by means of the centrifuge, is cooled down to zero, when the plasma rapidly becomes turbid, and a decided flocculent precipitate is formed. This is the body which gives rise to the fibrin ferment, and if examined microscopically the precipitate is found to consist of a number of minute transparent bodies, nearly circular in shape, but much smaller than the red corpuscle, and having a great tendency to run together into granular masses. These peculiar bodies may perhaps explain the granules, blood-plates, and hæmatoblasts of Osler, Bizzozero, and Hayem.

MESSES. CASSELL'S serial publications, which have obtained such universal popularity, continue to increase in number and variety. This month the first part of a new work entitled "Familiar Trees" makes its appearance, illustrated in that attractive style for which this house is so famous. We would, however, suggest that eight pages of a small crown 8vo text is hardly a sufficient supply of material for a month's reflection; at this rate also the book would take almost a lifetime to complete. The *Magazine of Art* issued from the same press is this month really charming. The serial, however, issued by this firm which will probably most interest medical men is the *Encyclopædic Dictionary*, which when completed will probably be the best book of reference of the class extant. The August part to hand takes us as far as the word "contagious," and contains interesting views and bibliographical references to such subjects as conception, consanguinity, consumption, contagion, &c.

THE seventh annual issue of *L'Année Médicale* has just reached us, edited by Dr. Bourneville, who so ably conducts

our Paris contemporary *Le Progrès Médical*. It conveys the impression of being a careful and conscientious *recueil* of the advances made in the various branches of professional study, but on a casual examination one is apt to infer either that English research has been feeble in its efforts, or comparatively sterile in its results during the past year. It would be invidious to hazard an opinion as to this, and it would perhaps be more charitable to ascribe the preponderance of French research and French discoveries to the *milieu* which has given it birth. In any case it is a compilation of great interest, and well worthy of perusal by those in whom the cares and anxieties of a general practice have not altogether stifled a scientific interest in their profession. We shall shortly furnish our readers with a *précis* of all that calls for special notice in this book.

HISTOHÆMATIN is the name given by Dr. MacMunn to a class of pigments, or modifications of the same pigments, which are widely distributed in the animal kingdom, and to which myohæmatin belongs. The histohæmatins are respiratory pigments, as can be proved by oxidising and reducing them in the solid organs. Their bands occupy almost the same place as those of myohæmatin. In the supra-renals of man, cat, and some other animals, the medulla gives the spectrum of hæmochromogen, while the cortex shows that of histohæmatin. Hæmochromogen in a vertebrate body is probably excretory, and must be so regarded here, hence the function of the adrenals must be (at least in a part) to metamorphose effete hæmoglobin or hæmatin into hæmochromogen. An active metabolic process takes place in the adrenals, and Dr. MacMunn concludes that they have a large share in the downward metamorphosis of effete colouring matter, and that his observations will help to throw some light on Addison's disease.

THE competition for the Professorship of Anatomy in the Owens College promises to be an animated one, several candidates of considerable reputation being in the field. Apart from local aspirants to the post, the principal competitor is Dr. W. P. Mears, who is at present in possession of the chair of Anatomy in Durham University School of Medicine, with which his connection has lasted for over seven years. In this time Dr. Mears has shown himself to be a most able and successful teacher, and, by the publication of his "Schematic Anatomy," original also. Under his fostering care the school at Newcastle-on-Tyne has rapidly increased in numbers and importance, and it will be a serious loss to it should Dr. Mears succeed in his candidature at Manchester, although the latter place would correspondingly benefit by his presence. The value of the professorship at Owens is £700, but as the office of Dean of the Medical School would probably be associated with it, the annual income of the holder would be increased by £150.

WE have before us a small "Students' Botany," by E. MacDowel Cosgrave, M.D., who, with a degree of modesty not very fashionable among authors, disclaims in his preface all pretensions to originality, choosing as his motto, "I have called a bouquet of varied flowers from men's gardens, and nothing is my own but the string that ties them." Still we are glad, after having our sympathies so awakened, to be able to say that our author's "aid" presents as much originality as is generally safe to give to a student's manual, in which we think the chief aim should be by judicious arrangement and simplicity of language to make the absorption and assimilation of the contained matter as easy as possible to the heavily burdened student who takes up the study of biology in the present day. We think that Dr. Cosgrave has done his work well; his definitions are clear and concise, his language pure and well chosen, and we trust that his book will be extensively used by the class of students for whom it is intended.

THE fifth edition of Squire's "Pharmacopœia of the London Hospitals" will be welcomed by those to whom the former issues have been found indispensable. Since the last edition appeared, five or six years ago, thirteen hospitals have published new Pharmacopœias, so that the present editors, the two sons of the lamented originator of the book, have had no easy task in bringing it into conformity with the numerous changes which have taken place. Of course in such a collec-

tion the information is often scattered, and not easy to collate. It might be interesting to some to compare the formulæ of new remedies or even of old ones in common use in hospitals. We tried this in the case of oleate of mercury. We found some hospitals content themselves to order hydrarg. oleat. of 5 or 10 per cent. Others give ungu. and more linim. So we must look for the formulæ under three heads. For some purposes this is inconvenient, but no other arrangement could have been adopted. If the editors would like to face the work of compiling an index of the drugs referring to the places where they are used it would be an admirable addition for some persons, but perhaps we can hardly expect this, as their work already so well answers the purpose for which it was designed.

If it were possible to regard the drawing-room table as an appropriate resting place for Mr. Treves' recently published Hunterian Lectures on "The Anatomy of the Intestinal Canal and Peritoneum in Man," it would be easy to understand the reason of the extraordinary form in which the work is issued; or the difficulty would be removed if we could conceive that the object of quarto pages, oceanic margins, ancient type, and lily white covers, was to lend grace and tenderness to the dry-as-dust details of anatomy. Mr. Treves, however, is not desirous of becoming a drawing-room author, nor can it be admitted for a moment that anything coming from his able pen needs any meretricious surrounding to command immediate success; consequently the issue of an *édition de luxe* of lectures on enteric anatomy must remain one of those obscure secrets which always exist as aids to the development of ingenuity. Notwithstanding their somewhat startling shape, however, the lectures are an admirable and most welcome contribution to the exact science of anatomy, and show the painstaking and laborious character of their author's patient investigations to advantage. They are fully worthy of Mr. Treves; than this they could not be praised more highly.

**NEW BOOKS AND NEW EDITIONS.**—The following have been received for review since the publication of our last list, June 17th:—Pathological Mycology, by G. S. Woodhead, M.D., and A. W. Hare, M.B. The Causes and Prevention of Blindness, by Dr. Fuchs, translated by Dr. Dudgeon. Gout in its Clinical Aspects, by J. Mortimer Granville, M.D. Suicide, by W. Wynn Westcott, M.B. Lond. Lectures on Diseases of the Brain, by W. R. Gowers, M.D., F.R.C.P. School Hygiene, by Robert Farquharson, M.P., M.D. On Dwellings, Healthy and Unhealthy, by Catherine Buckton. A Retrospect of Medicine, edited by James Braithwaite, M.D., Vol. XXI. Health Resorts at Home and Abroad, by M. Charteris, M.D. The Life and Letters of W. Fairlie Clarke, M.D. Tracheotomy in Laryngeal Diphtheria, by R. W. Parker. Guide to the Examination of the Urine (6th edit.), by J. Wickham Legg, F.R.C.P. Lond. The Anatomy of the Intestinal Canal and Peritoneum of Man, by F. Treves, F.R.C.S. Elements of Surgical Pathology, by A. J. Pepper, F.R.C.S.

**University of Glasgow.**—The following candidates having passed the necessary examinations, have received the degrees of M.B. and C.M. of this University:—Messrs. James R. M'Crimble, John A. M'Donald, Alex. M'Kean, C. A. M'Kechnie, John M'Keith, John M'Kie, James N. M'Lean, John A. M'Quarie, Charles M'Taggart, Henry J. Neilson, John F. Orr, James Parker, W. W. Paterson, Andrew Richmond, John Ritchie, J. A. Robertson, M.A.; James A. Robertson, David Roxburgh, Pramad N. Roy, Thomas Rutherford, B.A.; Walter Sandeman, Joseph Scanlan, Wm. M. Semple, J. C. A. Smith, and Gregory Sprott.

**Royal Colleges of Physicians and Surgeons, Edinburgh, and Faculty of Physicians and Surgeons, Glasgow.**—The examinations for the triple qualification of these bodies in Edinburgh were held in July, with the following results:—

**Passed First Examination:**—Charles Edward Dew, Henry Anthon Becker, Octavius Stevens Fisher, George James Scantlebury, John Charles Steedman, James Brown, Duncan McArthur, John Adams, George Watt Anderson, William Wheelwright Clegg, John Dicken Dale, Alexander Duncanson, Ellicourie Jocelyn Courtenay, Joshua Chadwick, James Alexander Greig, Charles Hicks, Francis Edward Hodder, Tom Hugh Jones, Harry Evelyn Mahonie, Thomas McGubbins, David Scott Moncrieff, James Wallace Lindsay, Henry Mathias, James McDiarmid, Harry Nesbit Robson, John Lewis Owen, Rupert George Naylor, Robert Johnson Pirie, Adam Ramage, Edgar D. Wellburn, Hugh Thomson, Robert Arthur St. Leger, and John Thomson.

**Passed Second Examination:**—William Wheelwright Clegg, Thomas Kensington James Fulton, Edward Taloon Hawkesworth, Ephraim Hilliard, Ellicourie Jocelyn Courtenay, James Gordon Mackintosh, Alexander Angus Martin, Thomas Lloyd Jones, Richard Markland, James Joseph McEniry, George Herbert Butler, William Murray Mackay, Thomas William Stewart, Sydney Rumbold, Frederick Moritz Sykes, Henry William Bryant, Hermann Gerhard Hilliers, Arthur Broadfield Frost, Charles Edward Dew, Joseph Septimus Fallon, Octavius Stevens Fisher, Tom Hugh Jones, Duncan McArthur, Edward Harkness, George James Scantlebury, Edgar Duesbury Wellburn, and Theodosius Thompson.

**Passed Third Examination, and admitted L.R.C.P. Edin., L.R.C.S. Edin., and U.F.P. & S. Glasgow:**—James Anderson, John Donaldson, John Horatio Drake, James Doyle, Joseph Septimus Fallon, Octavius Stevens Fisher, Arthur Broadfield Frost, Franzoni Antonino Faria, Arthur Morley, Murdoch Mackenzie, James Nesbitt, Caulce Joseph McGrath, James McKenzie, Viriato John Pinto, Herbert de Curle Woodcock, and Robert Stevenson Wadsworth.

**Royal Colleges of Physicians and Surgeons, Edinburgh.**—**DOUBLE QUALIFICATION.**—During the recent sittings of the examiners the following gentlemen passed their first professional examination:—

Allan Wise Clarke, William William Griffiths, and Robert Gascoigne Taylor.

The following gentlemen passed their final examination, and were admitted L.R.C.P. and L.R.C.S. Edinburgh:—

Charles Dundas Grant, Vernon Edmund Russel Ardagh, Benjamin Sidney Browne, John Robert Henry Duborg, Michael English, James William Fox, Charles O'Farrell, Harry Gordon Leigh-Gilchrist, Charles Louis Gabriel, Godfrey Ernest Garde, Henry Edward George Johnson, William Owen Magoria, George Thomas Hartley, Robert Morrison, James Joseph Moran, Patrick Hicks Moriarty, Robert Thomson Paton, John Godfrey Nixon, William Henry Roberts, George William Robinson, Herbert Toft Phillips Sinclair, William James Shell, Charles Augustus Thorne, William Overton, Robert Francis Martin Quin, and John Thomas.

**Royal College of Surgeons of Edinburgh.**—During the recent sittings of the examiners the following gentlemen passed the final Examination, and were Licentiates of the College:—

Luther Laurence Hooper, Neil Charles McKinnon, Joshua Jackson, James Lindsay, and William Jaques.

The following gentlemen passed the first professional examination for the Licence in Dental Surgery:—

Gordon Reid Shlach, Arthur Cocker, and Frank Gordon Allen.

The following gentlemen passed the final examination, and were admitted L.D.S. Edinburgh:—

Thomas Prettle Ritchie, David Browne, and Andrew Burns.

**Royal College of Surgeons in Ireland.**—The following candidates having passed the final examinations during the present month, have obtained the licence in Surgery of this College:—

Robert Abraham, George W. Armstrong, Thomas Browning, William G. Chute, Arthur E. T. Craig, Frederick A. Davis, George B. Elliott, Henry L. Finny, Henry C. Groves, Andrew Harris, Edward Heard, Gerard E. Irvine, John Keatly, Bernard F. Kennedy, Timothy Killeen, John E. McBride, Thomas D. Moors, Michael J. Morgan, Samuel F. Murphy, John W. Peacock, William G. Rutherford, William Stritch, John A. Whitty.

Of 46 candidates at this examination, 24 were rejected.

**The Mortality of Foreign Cities.**—The annual death-rate per 1,000 in the principal foreign cities, according to the last weekly returns communicated to the Registrar-General, are as follow:—Calcutta 22, Bombay 22, Madras 30, Paris 19, Geneva 17, Brussels 19, Amsterdam 21, Rotterdam 20, The Hague 16, Copenhagen 16, Stockholm 23, Christiania 17, St. Petersburg 27, Berlin 33, Hamburg 24, Dresden 24, Breslau 41, Munich 27, Vienna 28, Prague 35, Buda-Pesth 32, Rome 21, Turin 25, Venice 26, New York 25, Brooklyn 24, Philadelphia 22, and Baltimore 25.

**Vital Statistics.**—The deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 19.5 per 1,000 of their population, and were—Birkenhead 19, Birmingham 15, Blackburn 16, Bolton 17, Bradford 12, Brighton 13, Bristol 14, Cardiff 19, Derby 14, Dublin 27, Edinburgh 14, Glasgow 22, Halifax 11, Huddersfield 16, Hull 13, Leeds 18, Leicester 23, Liverpool 22, London 20, Manchester 23, Newcastle-upon-Tyne 16, Norwich 21, Nottingham 15, Oldham 16, Plymouth 25, Portsmouth 14, Preston 17, Salford 23, Sheffield 23, Sunderland 18, Wolverhampton 16. The highest annual death-rates from diseases of the zymotic class in these towns were—From measles, 1.7 in Sheffield, and 3.4 in Newcastle-upon-Tyne; from whooping-cough, 2.2 in Cardiff, 2.3 in Derby, 3.2 in Blackburn, and 3.4 in Birkenhead; from scarlet fever, 1.3 in Wolverhampton; from "fever," 1.0 in Newcastle-upon-Tyne; and from diarrhoea, 1.6 in Preston, 2.0 in Salford, 2.7 in London, and 9.6 in Leicester. The 24 deaths from diphtheria included 16 in London and 5 in Liverpool. Small-pox caused 19 deaths in London and its outer ring, 1 in Sheffield, and 1 in Sunderland.

## Notices to Correspondents.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**READING CASES.**—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

**LOCAL REPORTS AND NEWS.**—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

Dr. J. W. C. (Southsea).—We have not yet seen them.

MR. WILSON (Bath) will see the subject is referred to in another column. We think the discussion most unfortunate, and not warranted by existing circumstances.

MR. COGREAVE (Wandsworth).—Sorry we cannot add further to our free list. Were we to accede to your request, we might do the same to the hundreds of reading-rooms which exist in every large town.

L.R.C.P. (Liverpool).—The population of Liverpool exceeds that of Madrid by about 100,000. We are informed by a correspondent in the latter city that the cholera returns are much exaggerated for political purposes, it being thought that by keeping the excitement alive the people (headed by Carlist agitators) will have more important personal matters to think of than rebellion.

A THIRD YEAR'S MAN.—We understand that a new edition is in preparation, but that it is not likely to be issued before January next. Meanwhile, copies of the existing edition can be referred to at any of the public libraries.

OXONIUM.—No guide to the examinations in question is published, nor are the papers to be had, except as a matter of private favour. We regret, therefore, we cannot assist you.

DR. ALBERT.—When a practitioner invokes the assistance of one of his brethren to conduct a labour case in his absence, the usual rule is that the fee should be shared equally between them. There is nothing in the circumstances you mention to necessitate any departure from the custom obtaining in this respect.

### THE INFECTIOUSNESS OF SMALL-POX.

A CORRESPONDENT, "Q. E. D.," asks, in reference to the death of a sanitary inspector at Oundle, Northamptonshire, chronicled in our last (page 89), "Would it not be well in the present uncertain state of popular prejudice, to inquire into the fact whether the late sanitary inspector and others had been re-vaccinated?" It seems strange that the only "exempt assistant" at the aforesaid burial should be a "medical man." The corollary thereby attached would be that, even with the actual contact taking place with the defunct body, "what amount of immunity was present to protect the doctor?"

MR. DONALDSON.—We would willingly help you if we could. Publicity, however, would not advance your interests.

J. A. B.—There is no occasion for the observance of special rules under such circumstances. The case should be treated as an ordinary burn, and will do well.

DR. SIMPSON.—At the present time we are in receipt of more than one similar offer, but we do not yet see occasion to avail ourselves of the suggestion.

### FAITH-HEALING EXTRAORDINARY.

A. P. H. expresses the opinion, which will be generally endorsed, that the case quoted by a contemporary exemplifies many that could be (with a little care and trouble) brought before the public to expose the absurdity of the so-called "Faith-healing," and asks, "Is it not ridiculous that the well-founded diagnosis and prognosis of a well-qualified medical man should be opposed by an evil-disposed woman, who, taking the kudos, actually fulfils his prognosis?"

MR. BELLAMY.—Scarcely worth while to re-open the whole question.

A PROVINCIAL PRACTITIONER.—Whey-cures are far more popular on the Continent than milk-cures, though neither are so much in vogue now as during the last half-century. There is no material difference in the therapeutical action whether a patient take cow, goat, or ewe whey. Whey increases the secretions of the intestinal canal, the kidneys, and the skin, promoting the change of tissue; it also acts as a mild aperient. You should get one of the many small books on the subject.

MR. AMORY.—You will find all the questions you ask fully answered in our Students' Number. That for 1884 contains detailed information on the subject, and no important alterations have been made in connection with it since that number was published.

DR. GARDEN.—Many thanks for the communication, which, however, only the more strongly confirms us in the views we had formed. Should your suggestion be ultimately followed, the origin of the information will be fully acknowledged.

### THE MEDICAL RELIEF BILL IN THE LORDS.

MONDAY'S proceedings in connection with the Medical Relief Enfranchisement Bill in the House of Lords afforded another evidence of the bid for power now at fever-heat by the leaders of both political parties. Earls Granville and Milltown each sought to outbid the other for the privilege of introducing this, in many respects, objectionable measure, each contending that he had the right and title to move the second reading. Ultimately it was decided that the Earl of Milltown should have charge of it to-day (Wednesday).

DUBITANS.—We cannot undertake to determine the question without first receiving much more complete details than have yet been furnished. So far as it is possible to judge at present, both sides have been in fault; but whose fault is the greater seems open to discussion.

R. P.—You are not by any means alone in condemning the proceeding; and we are glad to receive so large an amount of support as is given to us on the steps we have taken. The matter is one of the utmost concern to every one anxious to preserve the moral prestige of the country.

DR. NANKIVELL.—We have no means of judging the relative values of the preparations. Any experiments conducted with a view to deciding the question will be valuable, and deserve every encouragement.

## Vacancies.

Clonmel District Lunatic Asylum.—Assistant to Resident Medical Superintendent. Salary, £150, with apartments, &c. Election August 10. (See advt.)

Dunfahugh Union, Crossroads Dispensary District.—Medical Officer. Salary, £110 and fees. Election August 5. (See advt.)

Ile of Man General Hospital and Dispensary.—Resident House Surgeon. Salary, £100, with gas, coal, &c. Applications, with testimonials, to the Hon. Sec., not later than August 10.

Mason Science College, Birmingham.—Demonstrator in Physiological Department. Applications on or before August 23.

Netherland Institution for Infectious Diseases, Liverpool.—Resident Medical Officer. Salary, £30 per annum, with board, &c. Applications, with testimonials, to the Secretary, on or before Aug. 1.

Ramsgate and St. Lawrence Royal Dispensary and Seaman's Infirmary.—Resident Medical Officer. Salary, £120 per year, with furnished apartments, &c. Applications, with testimonials, to the Secretary of the Dispensary, on or before August 1.

Royal College of Surgeons of England.—Examinership in Dental Surgery. Applications to the Secretary, before July 30. (See advt.)

Taunton Union, Churchstanton District.—Medical Officer. Salary, £22 per annum. Applications, with testimonials, to the Clerk, by August 1.

## Appointments.

BIDEN, C. W., M.R.C.S., L.R.C.P. Lond., House Surgeon to Charing Cross Hospital.

JENBY, T. C., M.D. Brux., M.R.C.S., L.S.A. Lond., Honorary Surgeon to the Bradford Infirmary.

GREENFEL, H. O., L.S.A. Lond., House Physician to Charing Cross Hospital.

HALL, C. B., M.D., M.Ch. Q.U.I., Medical Officer for the Dewsbury District of the Dewsbury Union.

HAW, W. H., M.R.C.S., L.S.A. Lond., Resident Obstetric Officer to Charing Cross Hospital.

LONDON, A. A., M.D. Lond., M.R.C.S., Medical Officer to the Sick Children's Hospital, Adelaide, South Australia.

LIDDELL, H. J. S., M.R.C.S., Medical Officer for the Buckland District of the Tavistock Union.

LONGHEAD, W. H., M.B., B.Ch. Durh., Medical Officer for the North Somercotes District of the Louth Union.

MCLAREN, M., B.A., M.B., C.M.Ed., & M.R.C.S., House Surgeon to the Bootle Borough Hospital, Liverpool.

NOBBURY, T. W., L.R.C.P. Ed., M.R.C.S., Medical Officer for the Stratford-on-Avon District.

STEEDMAN, F. O., M.R.C.S., L.S.A. Lond., House Surgeon to Charing Cross Hospital.

TRIBBLE, F. T., L.R.C.P. Lond., M.R.C.S., Honorary Surgeon to the Torbay Hospital, Torquay.

WALLINGTON, W. T., L.S.A. Lond., House Physician to Charing Cross Hospital.

## Births.

AUCHINCLOSS.—July 17, at 35 York Street, Dublin, the wife of Hugh A. Auchincloss, F.R.C.S.I., of a daughter.

CONSTABLE.—July 20, at 406 Mile End Road, London, E., the wife of Samuel Constable, L.S.A., of a daughter.

MILLER.—July 23, at Percy House, King's Cross, London, the wife of John A. Miller, L.R.C.P., M.R.C.S., of a son.

SANBORN.—July 21, at 84 Harley Street, London, W., the wife of Arthur Ernest Sanson, M.D., F.R.C.P. Lond., of a son.

## Marriages.

ADDINSELL-BLAND.—July 21, at Kensington Presbyterian Church, Augustus W. Addinell, M.B., of West Kensington, to Katherine Cotter Hamilton, third daughter of F. C. Bland, of Derriquin Castle, Co. Kerry.

MALONE-KAVANAGH.—July 23, M. J. Malone, M.D., F.R.C.S.I., of 5 Percy Square, Limerick, to Mary, daughter of the late Bernard Kavanagh, M.D.

RODWELL-O'LEARY.—July 22, at All Saints' Church, Kensington, Chas. E. Rodwell, of Ashleigh, Taunton, to Ellen Victoria, only child of Deputy Surgeon-General O'Leary, M.D., Army Medical Service (retired).

## Deaths.

ALLEN.—July 14, at his residence, Mooroot, Didsbury, near Manchester, Richard Allen, Surgeon, aged 75.

BROWN.—July 17, George Dransfield Brown, M.R.C.S., of Henley Villa, Ealing, aged 57.

HARDING.—July 12, at Exeter, Edward Hardinge, late Assist.-Surgeon R.H.A., fourth son of the late Rev. T. H. Hardinge, D.D., Rector of Ashley, Staffordshire.

### ON SOME CAUSES OF DISEASE, AND ON REPARATIVE AND DESTRUCTIVE PROCESSES.

An Address delivered at the Opening of the Section of Medicine at the Annual Meeting of the British Medical Association, held in Cardiff, July 29th, 1885.

By SAMUEL WILKS, M.D., LL.D., F.R.S.,  
Senior Physician to Guy's Hospital; President of the Section.

THE best method, I believe, to arrive at anyone's sentiments or opinions is to study his actions; and if I do this with myself, and look back to the addresses which I have given at this Association, at my hospital, or at the International Congress, I find the theme is the same. It is one which had its basis formed at a very early period of my career, and became more fixed as years and experience went on. It was this, that the peculiarity of different races of mankind must depend on climate, food, and other surroundings, and that these peculiarities are transmitted; that hereditary tendencies have, therefore, much to do with the physical and mental characters of individuals, and also that these temperaments and idiosyncrasies which are so evolved are most important in the production of our ailments; again, that these surroundings are, in themselves, sufficient to produce active disease—for example, a number of conditions tend to the prevalence of the gouty constitution in England, and this may be carried through several generations, but the same conditions, operating on an individual predisposed, may actually induce an attack in him: that the predisposing and exciting causes are the same. Morbus Brightii, and many other diseases, come about through the deleterious operation of our ordinary surroundings, both in the air we breathe and in the food we eat, and not from any well-defined specific cause. I have, therefore, considered that nearly all disease is slow in its origin and progress, and I have never been tired of quoting Hippocrates, the father of medicine, who said, "Diseases do not fall upon men instantaneously, but being collected by slow degrees, they explode with accumulated force." I thought I saw, even in my student days, how erroneous the books and lectures were in giving descriptions of acute diseases as occurring in

healthy persons, and then how such affections became at last chronic. The truth, as I saw it, was very early forced upon me by making post-mortem examinations; when, for example, a person was brought to the hospital for obstruction of the bowels, attributed to an intussusception, or the lodgment of some indigestible food, and which proved nearly always to be due to a cause of very long standing, or even congenital; in the same way acute peritonitis was but the termination of some old disease in the abdomen, and a meningitis the ending of a prior disease in the brain. I had thus come to look upon disease as essentially chronic in its nature, induced by the ordinary agents surrounding us, and to believe that the medical art should be mainly directed against the operation of these causes. I have no doubt, had I given an address, and shut my eyes to all the discoveries going on around me, I should have wandered back to the old theme, and found all my opinions confirmed by age. I cannot, however, be blind to what is now occupying the medical mind, and therefore with all sadness confess the truth, my occupation's gone. It is of no use talking any longer of the conditions of our climate predisposing to phthisis; of the hereditary tendency to this disease, much less of any peculiar conformation of chest and frame in those who fell a prey to it, for the disease is due to a bacillus, which may be taken by a husband from his wife, or *vice versa*, or conveyed by a phthisical nurse to a number of children whom she suckles, or even, indeed, caught in the street; at least, this was suggested in the case of a lad who died of tubercular meningitis, having long had a sore tongue, which was called tubercular. It was surmised that it was primarily a simple ulcer, on which bacilli alighted as he walked through the streets. In order to mollify believers in predisposition, temperaments, and configuration, it is admitted that there must be appropriate soil for the cultivation of the germs; but, after the delivery of these platitudes, they are put on one side for the study of the one potent agent, the bacillus, and are no more considered than predispositions to small-pox, scarlatina, or cholera. I do not for a moment attempt to throw any discredit on modern research, for these bacilli undoubtedly exist, as any one may prove for himself; but I am rather offering myself for pity, that, having preached on one long text, that it is the great aim of the physician to seek the causes of the disease in our ordinary surroundings, and in the tendencies transmitted to us, and to try to remove them, I find my occupation gone;

but perhaps I am only shunted for a time to let the express pass by.

It might be worthy to remark, in passing, how treatment accompanies and follows pathological discoveries, in opposition to the mistaken idea, which many seem to hold, that there is a science of therapeutics gained by a simple observation of the action of drugs on the body. It is sometimes said that therapeutics stands still or lags behind other departments of medicine. I think this is not true, nor cannot be true; in fact, I am at a loss to know what pure therapeutics is, apart from disease and pathological states. It seems to me it is the study of external agents on various diseased conditions; and it is not so much new remedies, but a better indication and knowledge of how and when to use them, which is required. For example, thousands of persons are now cured of nervous diseases, not by a new remedy, but by the old iodide of potassium, and this was done as soon as pathology had discovered the existence of visceral syphilis. So, in the same way, if the doctrine of bacillary phthisis is true, we have our antiseptics at hand, and we have not had to wait for iodoform, eucalyptus, and benzoic acid, and such like remedies which are now in vogue. The improved treatment in the one case came from observations in the post-mortem room, and in the other from the pathological laboratory. If there be one-tenth of truth in the value of the remedies which we see weekly vaunted in the advertisement pages of the medical journals, therapeutics has shot far ahead of every other branch of medicine.

I might here allude to the fact that the discovery of germs in phthisis and some other complaints will probably oblige us to give up our old theoretical notions as regards the pathology of the exanthemata and other specific diseases. It is in these diseases, which are called zymotic, that no microbes have been found. It will be remembered how Liebig marked the resemblance of the course of a specific disease like small-pox to the process of vinous or acetous fermentation. When, for example, an organism is placed in a saccharine fluid, it begins to develop and grow until all the pabulum on which its multiplication depends has disappeared. The fermentative process, therefore, must cease, and cannot occur again in that fluid. In a similar way, a virus inoculated into the human body continues to develop during a certain term, called the period of incubation, and then rapidly multiplies a millionfold, accompanied by a great commotion in the whole system, when the process ceases, and is never capable of occurring again. The likeness to the fermentative process so struck Liebig, that he introduced the term zymotic for this class of disease, and it has been made use of ever since. The theory may be rational, but it is very remarkable that it is in these very diseases, whose course would have suggested the growth of some organism like a ferment, that this has not been found—I allude to typhus fever, small-pox, scarlatina, &c.; whilst, on the other hand, in diseases where no analogy can be traced between their symptoms and the fermentative process, microbes have been discovered, as in cholera. Here patients are sometimes suddenly stricken down, and die in a few hours, without any of those previous conditions which in any way resemble the stages of a fermentative process. In phthisis, again, there is no analogy between the symptoms and those of a specific disease where germs have been supposed to be present, since the disease may remain for a long time local, and the blood be unaffected. All modern discoveries regarding microscopic organisms do much to overthrow the zymotic theory of disease, were it not, indeed, under any circumstances, too extravagant an one to hold—a theory suggesting that there are several substances in the blood too subtle to be recognised by any known methods, but affording a pabulum for the growth of germs of small-pox, scarlatina, and such like diseases, when they fall upon us, and that this is the only use of those imaginary constituents of the system. It is a great pity that any word like zymotic, implying a theory of disease, should ever have been allowed to enter our nomenclature. Hitherto, no antiseptic or specific remedy has been found to prevail against the regular course of these diseases, and one reason may be that the enemy to be attacked was an imaginary one; but from this it does not follow that antiseptics may not be of service in diseases where organisms have been found. I will not dilate more upon this subject, but feel it quite impossible for any one who was making medicine the subject of his discourse to overlook the fact, that all pathological enterprise is now engaged in the search for

specific causes of diseases, and to found a treatment upon it. This has rendered the pathology of many diseases much more difficult to understand, since it is almost impossible to graft the new facts upon the old, or even reconcile them with those which are already established.

Amongst many other subjects in medicine of a general nature to which my thoughts have been directed, there is one with which I will occupy you during the remainder of the short time allotted to me. It is a subject which has two sides to it—a physiological and a pathological one—both highly important with reference to clinical medicine. The one aspect has reference to the mutual relation which exists between the different functions of the body, suggestive of the organs having varying activities and compensating actions; the other aspect is the compensating or actual conservative process which we see going on during the progress of many diseases, a reparative as well as destructive action, and which can be recognised clinically during the life of the patient.

The readers of the lectures of Sir James Paget will remember how he dilates upon a law (which had already been formulated by the older masters in medicine) that the proper adjustment of the various functions of the body is necessary for its integrity; and in this way every physiological process, however slight, may be looked upon in the light of a natural secretion. This seems like a truism, or mere platitude, and yet it is not seriously or practically considered. To preserve the integrity of the body of a given bulk, so much pure blood is required, and, therefore, suitable organs of a certain size for its production, also a definite amount of depurative organism for its purification. In this way life goes on.

It is so evident that the organs must be proportioned to their use, that Aristotle maintained that Nature makes the organ for the function, and not the function for the organ. One of the most striking examples of this law is seen in the case of the kidneys. If one kidney be destroyed from any cause, the other will enlarge to compensate for the loss. It will grow until it has reached the point necessary for the discharge of its duties, and then cease to enlarge.

The same probably occurs in other organs; where, for instance, a portion of the liver has been destroyed, the other lobe has proportionally enlarged; and, in some chronic affections of one lung, the other one has evidently grown to maintain the balance. These processes are evidently conservative, and indicate a healthy organism. But it may be as well to ask, Does a deviation from this line ever occur from some unknown cause, and in this way is an abnormal, or pathological, condition set up? As regards the former, that is, an increased or diminished function, I do not know that this has ever been suggested in the more complex vital organs, and yet of late years a hypertrophy of the liver has been spoken of by pathologists. It is true that the term is given simply to express certain anatomical changes, and not necessarily implying that there has been an excess of the original secreting organ.

As regards less important viscera and structures, it would seem that this limitation to healthy size is not kept; and in the case of the spleen the organ may grow to an immense bulk. Apparently the structure is healthy, and, putting together its supposed function and the state of the blood, it seems as if the balance was upset by the excessive development of one function, and the patient dies from having too much spleen. The same is thought to occur in the lymphatic glands, when they grow to immense size by the addition of apparently healthy tissue.

Another structure which sometimes will start into growth without any relation to the original framework is the bony skeleton, the skull, and all the long bones reaching an enormous size and weight; so also the skin and fat develop until the person is of great bulk. Those are cases which, in a marked degree, show that there are causes in operation which sometimes upset the balance of growth and the fair relation between all parts of the body.

Now it is worthy of consideration to inquire whether, when the balance is upset by the disease or destruction of organs, any other organs or tissue may take on their extra work. For example, we sometimes find the kidneys so exceedingly atrophied from disease that we are at a loss to understand how life could have existed with so small a renal structure; if in health, four or six times that amount is necessary. Must it not have happened that other organs assisted in their work, notably the skin and intestinal canal; and may not the record be true that, under these circum-

stances, urine has been excreted by the nipples and other parts of the body?

The liver, too, is sometimes found so small and hard, that it is not difficult to understand why its possessor is dead, but why he should have lived so long. In this case, the purpurine in the water would suggest that fresh chemical actions have been in operation. As regards organs which are not vital, peculiar effects may be observed in the system when they are destroyed, as in wasting of the thyroid body, of the testes, or of the supra-renal capsules. We ask ourselves in what way is compensation made when an organ is diseased, and an answer to this question is what the judicious physician should try to discover, so that, by following Nature's laws, he may lengthen the days of his patient. I have observed that the most judicious medical men are those who will take the body as a whole, the good and bad, observe all the different functions, and so, by simple methods, rule and guide the whole bodily organism, so as to bring it to a proper adjustment. I need not remind you that they could not have been specialists.

Now, when one organ is actually diseased, it is very clear that the balance is upset, but it is equally important to ascertain whether a temporary cessation of function may occur from the operation of any external agent, and so a like disturbance occur. The importance of this question will at once be made clear to you when I ask you to direct your memories to a paper read before one of the medical societies by Sir Andrew Clark, and entitled *Renal Inadequacy*. The author spoke of cases where the renal secretion had become in every way defective, with corresponding symptoms. The subject debated was whether such temporary abeyance of function could occur in a healthy organ, or whether it must not imply disease. The subject was so differently considered by various members of the society, as to show that this had never been thoroughly investigated. It is true there may be an excess of urine passed; but, if this hold the proportionate amount of solid matter, it shows only that more work is put upon the organ, and not that it in any undue way is depriving the system of more solid constituents than is required. If, however, there be a large excess of water alone, it does generally show a temporary excessive action of the kidneys, and this is usually due to a nerve cause.

It is curious that there is a widespread popular belief in the ever varying action of organs; as, for example, we daily hear of a liver being torpid, or secreting an excessive amount of bile. Bernard's theory of diabetes was that it was merely an excess of a normal function, that the liver was over active in its glycogenic function. There is also a belief that the degrees of action of the liver are influenced by cold and heat.

In some organs, the action is clearly intermittent. In the case of the stomach, the organ when quiescent is small, containing little blood, and secreting no acid juice. As soon as it is stimulated by food, it enlarges, blood is poured into its walls, and an intensely acid juice is exuded from its mucous surface. The generative organs are more marked examples of the intermittent action, especially in women; but in man, everyone must know instances where a testis may be discharging its secretion every few days, and then be in abeyance for months or years. The lacrymal gland may, under emotion, pour out as much fluid in a week as at other times it would do in a year. The brain during sleeping and waking constitutes, of course, a well marked example of the intermittent actions of organs. During violent exercise, it is evident that the organs are more fully at work; there is more tissue-change, and more heat is produced; the skin is acting profusely, and the lungs more vigorously. As regards the brain, we may go a step further; there is not only the general inactivity during sleep, but there probably is in all of us more or less inactivity during our waking hours. If a person be taken from a savage or uncivilised country, and his mental powers can be well defined, and he be placed in a school, and be educated, so that after a time he shows himself possessed of considerable amount of intellect, we are bound to conclude that, if he had remained in his own country, he would have been in possession of an unused brain or a non-functioning organ. Must then the popular belief receive the sanction of the profession, that the liver may be torpid, the stomach inactive, the bowels sluggish, and the nerves unstrung?

Apart from the question of their own individual waking or sleeping, as they are in action or not, it might be interest-

ing to know whether the function of organs is influenced during ordinary sleep, or the sleep of the brain. Seeing that they are under the influence of the nervous system, this might be supposed; but since it is clear that the circulation is affected during sleep, it is almost certain that their action must be altered. Not only the brain sleeps, but other portions of the nervous system in part. It is said that the spinal system never sleeps, or the patient would die. Perhaps sometimes it does sleep, with the inevitable result. That it partially sleeps is seen in the paralysis of the whole muscular system when the head and the limbs fall, and the mouth drops, counterfeiting death; snoring also being a counterpart of the apoplectic stertor. In heart-disease, the state of sleep evidently involves to a certain extent the spinal cord, for the interference with respiration and the gasping are among the most distressing symptoms of this complaint. But more observations are required to ascertain the state of the vascular system during sleep. At present we must be content with the facts which are presented to us. These do not accord with our preconceived ideas, which are so strongly impressed upon us, that we act upon them rather than upon experience. The idea of sleep suggests quiet and repose, therefore the blood is circulating placidly through the body, and there would not be the same pressure on the vascular walls as during violent exercise. But is this warranted by facts? For example, are varicose veins found in those who are sedentary, or in those who take much exercise? A more important case is that of hæmoptysis in pulmonary disease, where hæmorrhage occurs much more frequently during the night, after several hours of rest, than during any exertion in the day. It is now many years ago I made this statement, which seemed to be absolutely true, when I was censured by a specialist for having maintained this before students, since it was obvious, he said, that there must be greater proneness to hæmorrhage during exertion. This opposition naturally made me observe still more narrowly, when I was more than confirmed in my original statement by discovering it was the rule for hæmorrhage to occur in the night. I can only surmise that, during the quiet of sleep, the circulation is more impeded, and the tension on the vessels greater, than when the lungs are expanding, and the circulation free. If this be so, why should purely theoretic or imaginary reasons guide us in practice, and oblige us to frighten our patient suffering from hæmoptysis by telling him he must not make the slightest movements with his arms, must not move out of bed, or speak above a whisper? I have never yet met a medical man who has told me that he is acting on other than theoretic reasons by so doing, and he has no proof that this quieting and frightening method is the best.

Then, again, take the heart; is it not during sleep that the patient suffers most, and is it not during the night that a weak heart may rupture, or an aneurysm give way? I have known a patient with mitral disease and a quick acting irregular heart gain much by a little exercise: a few paces around the room have quieted and slowed the action of the organ. Many persons are kept in a state of perpetual terror, and become hypochondriacal, because the medical man has forbidden all movement, even in their house, and they have been carried up and downstairs in a chair.

If we look to sanguineous apoplexy, I cannot say what the proportion of attacks is during the quiet of night and the active pursuits of the day. I myself am impressed with the great frequency of attacks during the night. Of course many other causes may be in operation during the sleeping hours, as, for example, the cooling of the body towards the morning. It is then that the medical man is aroused by his night-bell during cholera epidemics, and it is then that other temporary troubles connected with the digestive organs occur. The altered circulation, no doubt, is the cause of epilepsy occurring in some persons during sleep, and the supine position may perhaps be the cause of many back-aches being worse at night, as well as increased irritability of the bladder and other troubles.

There are many other interesting questions connected with the sleeping state which might throw a light upon the cause of some maladies. For example, headache in many persons is intimately associated with sleep at night and somnolency generally. Now, if it be true, as appears from many considerations to be, that the brain is less vascular during sleep, it would show that headache depends upon the state of the circulation. It may be true that the quiet of sleep may remove many headaches, but it is also true that a

heavy sleep is often followed by headache. I am aware of this personally, and can quite sympathise with a member of this Association who, in describing his own case a short time ago in the *Journal*, said that, after a hard day's work, when a feeling of sleepiness came over him, he hailed with delight the ring of the night-bell which was to keep him from his bed, and at the same time prevent the headache on the following morning. I know myself this evil side of sleep too well; and this, and others which I have depicted, are a few of the troubles which may arise during this time. It is true that sleep is "Nature's nurse," is "Nature's sweet restorer," and "the comforter when it visits sorrow," and is one of the best symptoms of the well-doing of the patient, so that, as perhaps you may observe in those obscure bulletins which issue from the fashionable medical men, the only information vouchsafed for the information of the public is that the patient has had a good night or restless night; but a sound sleep is not always good, and there is many a patient who can exclaim with Coleridge—

"Sleep, the wide blessing, seemed to me  
Distemper's worst calamity."

The subject of which I am here speaking is somewhat vague, and I regret I had not an opportunity of bringing more substantial facts before you. I must be content, therefore, with saying that the varying activity of organs during the day and night, and under different conditions, is one which more thoroughly deserves our attention. The subject is, no doubt, physiological in the first instance, but is, nevertheless, highly important to us as practising medical men.

I will now briefly allude to the purely pathological part of the compensating function to which I have here alluded, that is, the conservative or reparative processes, which are seen going on hand in hand with the destructive ones. In examining a diseased organ we do not sufficiently distinguish between the two processes; much less do we do so during the life of the patient. There is no doubt some general law in operation which provides for the two kinds of action, the formative and destructive; but the opportunity does not serve to discuss the question of correlation of forces, and how far we may regard all processes going on in the body as of two kinds, vital and chemical, mutually opposed. In an ulcer, certainly, the two processes are very apparent; there is the disintegration going on, and also the formation seen in the cells and granulations. A very valuable and scientific paper on this subject is to be found in the "Guy's Hospital Reports" by Mr. Golding-Bird. It wants but a moment's consideration to see how all organic life on the globe is necessarily associated with death, and that the same law is in operation in pathological processes.

Let me for a moment suggest to you my meaning. Let there be a softening or destruction of the brain; we find it surrounded by a formative cyst or inflammatory products; and, in the syringo-myelitis of the cord, the same thing is seen, large cavities associated with new products. It should be remarked, however, that, although reparation is going on, it is only by the formation of the simplest material; the highly complex structures are never renewed (except, perhaps, in children under special conditions); no injury to any of the parenchymatous organs is replenished by the same material, the repair is made by simple fibre. Bone may be replaced, and skin in an imperfect manner. In the case of the lung, the two processes, destructive and reparative, are always seen together; indeed, an ordinary phthisical lung could never have been witnessed without the double process. The ulcerated tissue would have produced a fatal hemorrhage or pneumothorax long before any extensive change could have occurred in the lung; but the vessel becomes closed, and the lung adherent. Now, the more chronic the case, the more are these reparative conditions marked, so that the pleura becomes greatly thickened, much of the pulmonary tissue cicatricial, and the cavity becomes lined with a firm membrane. Under these circumstances, we say that the signs of phthisis are well marked, the dullness on percussion is extreme, there is a falling in under the clavicle, and the pectoriloquy is pronounced. These are not so much signs of disease as of repair or cure. This is the reason why the young practitioner in such a case gives an unfavourable prognosis, forgetting the meaning of the signs, and, to his astonishment, may find his patient in much the same state a year afterwards. It is worthy of note that fatal hæmoptysis rarely occurs from the destructive process; it is due to the giving way of a dilated vessel in a localised and very chronically affected part of the lung. The same

probably occurs oftener than is supposed in the stomach; the chronic ulcer is characterised not so much by the destruction of the tissue as by the new growth around it; and it is in connection with this that the vessel becomes expanded and thinned, and subsequently ruptures. In cases of scirrhus pylorus it is quite as much the hypertrophied natural tissue which constitutes the tumour as the adventitious substance.

In the case of the liver, it is often difficult to say what changes are reparative or constructive, and which destructive. As the liver wastes, we observe a large concourse of veins on the surface of the abdomen, and we regard these as one of the signs of cirrhosis; but it is rather to be regarded as a consequence of the disease than one of its constituent parts. For, while the liver is being compressed, new blood-vessels and new bile-ducts are being formed, and the blood from the portal vessels, which would otherwise be arrested, makes its way to the surface and systemic veins, through the opening out of the old umbilical vein. The case of cirrhosis is a marked example of what I have been saying of the ulcer, whose description would demand demonstration of both a destructive and a formative process; but, in the case of the liver, where the change is so complex, it would be difficult to draw the line; many of these changes, however, are clearly no part of the primary pathological process. I have seen it stated, but I do not know with what authority, that, if the pulmonary arteries be injected in phthisical lungs before removal from the body, the injection may extend into the chest-walls through newly formed vessels. I may take another example in the case of the pseudo-hypertrophic paralysis of children. Now, in all the cases which I have seen, there has been a marked atrophy of the muscles, so that parts are wasted whilst others are enlarged, giving a general deformity to the whole body. In those limbs, too, which are hypertrophied, there is often perfect helplessness, showing that the natural muscular tissue must have undergone a decay. In the case of a boy lately under my care in Guy's Hospital, the difference in the size of the legs was most remarkable, one being three or four times the size of the other, but they were both equally helpless. The one showed merely wasted muscles, the other was firm from the production of new false tissue. The arms were wasted, and yet large masses of new tissue were felt in the deltoid and biceps. In these cases there is atrophy of muscular tissue, but, besides this, there is what is never observed in the adult, a productive process going on at the same time; the latter, however, has not the power to reach to the development of muscle, but remains in its lower state of fibre only. The example, however, is a striking one of the productive process going on with the atrophic one. In the case of the blood-vessels, degenerative and productive processes are constantly seen progressing together. In the cancers and other tumours of bones we perceive a destruction of the original tissue, and yet new bone growing up in the tumour.

You must forgive me for these few desultory remarks. I should have liked, had time and opportunity served, to have offered to your notice some well-developed theme; but I had on the present occasion no other resource than to look around me, and see what subjects had occupied my thoughts; one or two of them, although crudely brought before you, are, I think, worthy of your consideration.

#### ON INJURIES OF THE SKELETON, AND THE VALUE OF ACCUMULATION OF SPECIMENS.

*An Address Delivered at the Opening of the Section of Surgery at the Annual Meeting of the British Medical Association, held in Cardiff, July 30th, 1885.*

By EDWARD H. BENNETT, M.D.,

Professor of Surgery in Trinity College, and Surgeon to St. Patrick's Dun's Hospital, Dublin; President of the Section.

My first duty on taking the chair is to offer a welcome, on the part of the officers of this Section, to our distinguished foreign *confrères* and the goodly array of members of the Association who have given us their zealous aid, both by their presence and by their labour. Personally, I desire to express to the Council of the Association my sense of the honour they have conferred on me by asking me to preside in this Section. I trust that, by my conduct in the chair, I

may be able to maintain the fair fame of Irish surgery—a duty to which I am doubly bound, by virtue of the allegiance I owe to the Royal College of Surgeons in Ireland, whose president I have lately been, and again to the University of Dublin, whose professorship of surgery has been in my hands now for many years.

I propose, in the few words with which I shall detain the Section, to deal only with the subject with which I am myself most familiar, and to which I have devoted most of my work. I mean the pathological and clinical study of injuries of the skeleton. I think I can show that real progress here is to be made, not by the study of rare and attractive specimens and cases, but by the accumulation of large numbers of examples of ordinary injuries, and, above all, by laying down the rule, never to reject or throw away such things as appear to possess no interest. I have often been asked, what is the use of taking up space with such numbers of duplicate specimens as the museum under my direction in the University of Dublin contains? To such I have always answered that, only by the examination of a large number of individual specimens, can the details of any typical injury be worked out. I hope to show that, by this means, not only can the details of familiar injuries be rendered more complete, but new types can be discovered.

I may briefly refer, as an example, to the facts relating to Colles's fracture of the radius, which I was able to bring before this Association at the meeting in Cork in 1880. I showed then fifty-four specimens of this injury, and demonstrated that, among these, twenty-three gave proof of having been impacted fractures, while thirty-one were injuries in which positive evidences of impaction were absent. Since the time of that communication, our collection has grown to 100, this number being reached only within the last few days. We now find that the figures stand relatively forty-eight and fifty-two; and so, perhaps, the truth is more nearly reached. We have ample evidence before us in these facts, to put aside alike the opinions of Voillemier and of Smith; and we must be prepared, in practice, to meet these two conditions of the fracture in almost equal numbers. I speak on this matter with great deference to the illustrious names I have quoted. The merit of the first step in the investigation Smith rightly attributes to Voillemier, he being the first to demonstrate the constancy of the details disclosed by a section of the united fracture. From Smith's statements the conclusion has been drawn by many that no such thing as impaction exists in the fracture. Between these contending views nothing but the appeal to a large number of facts could decide. I found it all the more difficult to enter into the contest, for I was brought up as a pupil of Smith, learned from him for many years as a colleague, and have succeeded him in his professorship. I hold in these matters, however, that we must follow the Horatian maxim, "Nullius in verba magistri."

In another group of injuries—fractures of the ribs—my investigation of a great series of specimens has led me to endorse, in opposition to the commonly accepted theory, the opinion of Malgaigne, which seems never to have taken hold of the profession. Our standard text-books to this day, in this country and America, hold fast to the theory of Petit, which assumes that, when the chest-wall is broken by indirect violence, when the ribs break as the result of compression of the chest, as a whole their fragments are thrust outwards. Not a clinical observation or a specimen that I know of, confirms this view, and yet I say it is taught everywhere. Let any one who seeks to verify its value examine some hundreds of rib-fractures, and his views will soon change.

Similarly, some mystery attaches to fractures of the costal cartilages, chiefly because they had attracted but little notice until the beginning of the present century, when Lobstein directed attention to their peculiar mode of union by bone. This mystery is only the result of want of observation—it is said they are very rare. In 1865 the total record of such numbered thirty. Well, they cannot be very rare, seeing that I have myself observed some twenty-five examples dissecting and preserving of these fifteen specimens, all of which go to prove that only in the peculiarity of cartilage uniting by a structure different from itself does this fracture differ from that of bone.

But I may not delay the Section over examples of this kind. I must pass on to show how the mere preservation of specimens apparently uninteresting and unimportant can lead the way to useful results; and direct clinical observa-

tion. If I place before the meeting a single specimen of broken fibula, such as the diagram represents, such as any single one of the series on the table is, most men conversant with surgical pathology will pass it by as worth very little indeed. So did I; only I put these safely by as they came. After a time I found that their increase in number demanded attention. Every one knows the great importance that attaches to fractures of the lower end of the fibula, their great surgical interest, the writings of Pott and of Dupuytren. In all these and elsewhere no mention is made of fracture of the upper third of the bone, except as it occurs as an element of fracture of both bones of the leg, or with a complete diastasis of the bones at the ankle.

In looking over these specimens, I was struck with the fact that one feature was constant with them all, a fracture of great obliquity, but without material displacement. What was the cause? Certainly not casual direct injury. Going on with my study, I was not long in finding evidences that the injury was in some way associated with lesion of the ankle-joint; in some, a very special fracture of the tibia exists, which, when present, is alike in all. In others, evidence of past traumatic inflammation of the bones at the ankle bear testimony to the origin of the force from the ankle. In one the fracture is associated with fracture at the usual site of Pott's fracture in the lower third. I could produce several fractures of the fibula in the upper third similar to these, where, unfortunately, the tibia has not been preserved, which I doubt are not of the same type, for the extreme obliquity without displacement is quite distinct from the form of lesion which goes with fracture of both bones. Any way the number is remarkable, ten in all, where both bones are preserved. Seeing these facts I could not doubt that the injury, although unfamiliar to me as a clinical observation, must be sufficiently common. I was not long on this track before I found what I wanted. This case I published in 1880. I will now give an example observed by my colleagues in Sir Peter Dun's Hospital, and so free from the objection that might be advanced against myself on the score of prejudice.

"A man slipped in carrying a sack of grain down a sloping plank in unloading a vessel. His foot was suddenly checked in its slide by some irregularity of the plank, and he fell, conscious that something had given way in his leg. He did not strike or hurt his leg otherwise in the fall. Admitted to hospital, as he was unable to bear weight on the limb, he presented the ordinary features of a sprained ankle, without the ordinary signs of fracture of the ankle-bones. Treated for sprain, the case attracted but little attention for several days, when the circumstance of ecchymosis, high up in the limb, attracted notice. On this part being examined, the localised pain and crepitus peculiar to fracture left no room for doubt as to the diagnosis."

Somebody will say, Of what value is the observation? the bones unite well, and without deformity. So it does; but I hold that we surgeons, for our own sakes, if not for the sake of our patients, should avoid every error of diagnosis. Certainly, the surgeon who treats a sprained ankle for a week or a fortnight only to find it necessary to confess the existence of a fracture at that date, discovered by himself or another, does not feel pleased or proud of his skill in diagnosis.

I will only note further that this injury seems, as far as I have seen it in the living, to result, as in this case, from a sudden jar or wrench while the foot is fully extended.

I now will detain the Section only for a few moments while I give one other example of the benefit which the preserving of every even the least interesting of specimens yields. I may so show that, in mentioning these matters, I do not seek to sound my own trumpet, for the results are only the direct result of the method I have followed; with the clinical and pathological opportunities afforded by my position, and this mode of study, it needs little originality to see the family likeness connecting typical groups. Passing in review each series of pathological specimens, I laid aside the few examples of united fractures of the metacarpal bones in our collection, waiting until their larger and more important neighbours could be arranged. The small size of the bones, and the light value, clinically, which we surgeons have been apt to assign to simple fractures of the metacarpus, delayed my study of them, and so, perhaps, the result has been all the better; for, without some time spent in accumulating, a number sufficient to attract attention could not have been reached.

Taking at last the group into closer study, I was struck by the fact that one particular fracture outnumbered all others.

Malgaigne and Hulke have both asserted that the fracture of the metacarpal bone of the thumb is more common than that of any other of these bones, opposing the views of Boyer, who assigns the premier place to the fifth. The site of the fracture in the individual bones is set down as being "just above the middle," "in the middle or distal third."

Now, if we look to the series before us, a remarkable fact is disclosed. Amongst these fractures, there occur six examples of fracture of the base of the metacarpal of the right thumb, and no others of this bone. In each of these, the injury is the same—an oblique fracture, detaching the palmar half or more of the articular surface which faces the trapezium, with that projection of the base of the bone into the palm which supports the surface. The entire bone, except the little piece so separated, slips backwards, simulating in the living a subluxation of the bone in the direction. The appearance in the living of a subluxation is confirmed by measurement; for, as the fracture does not implicate the dorsal surface of the bone, the length on this aspect is unaltered.

When I published my first note on this injury in 1879, I had but the experience of a single clinical observation, and so I spoke with but little confidence about it. Since then, and as the immediate result of my publication, I have seen a great number of examples both of the recent injury and of the united fracture. Most remarkable is the fact that in every case the accident has been on the right side of the body. Certainly this injury, once we know of its existence, becomes vastly more common than any other of the metacarpus. If left to itself, it unites with such deformity as this cast shows—a trivial deformity, after all. Why, then, deem the matter worthy of the notice of this Surgical Section of the British Medical Association? Simply for this reason, that I have ample proof that a hand so injured remains, under the best of treatment, long disabled, and, without treatment, for a greatly longer time. When we consider the value of the right thumb to anyone who lives by handicraft, or indeed to any, rich or poor, we should not let pass unnoticed and undiagnosed this common injury. One point I have omitted to mention—the cause. In every case but one which I have seen, the case has been a fall which might well have broken the radius, but some slight deviation has directed its force against the thumb. Once I have seen it as the result of a blow of the fist against the jaw of an adversary in a fight.

I have already mentioned the essential features of the injury. One word as to the reason why probably it has long escaped notice. The pain and swelling of a sprained thumb are familiar to all, and prevent the ready appreciation of crepitus in the recent injury; but this may be found readily if pressure be made on the base of the bone from palm to dorsum, while a slight traction is made, sufficient to reduce the large fragment into place. I am confident that, before long, many of my hearers will test this matter for themselves, and perhaps then excuse my weary discourse to-day.

I have said enough to establish the merit of patient and diligent pathological study, combined with clinical observation.

## HISTORY OF THE PROGRESS OF LARYNGOLOGY FROM THE EARLIEST TIMES TO THE PRESENT.

By GORDON HOLMES, M.D.,

Physician to the Municipal Throat and Ear Infirmary, London;  
Consulting Physician to the Sheffield Ear and Throat Hospital.

Il importe beaucoup de connaître l'histoire de la science à laquelle on s'attache.—Boerhaave.

### EPOCH I.—THE PRE-LARYNGOSCOPIC AGE.

(Continued from page 98.)

*Physiology.*—This period was prolific in theories of voice-production, but as acoustical science was scarcely born, and ocular observation of the glottis in life unattained, the main body of fanciful and often conflicting theories con-

tributed but little to progress. A very small space need therefore, be devoted to the bulk of these hypotheses, and it will suffice to say that the prevalent opinion, in reality a reflection of that of Galen, was that phonation was effected by bringing the vocal bands within a short distance of each other, whilst pitch was regulated by the length and breadth of the interval. At the same time doubts were held as to whether variations in the capacity of the vocal tubes (trachea, pharynx, &c.) were not the main factor in determining gravity and acuteness of voice.

With respect to the action of the laryngeal muscles, Vesalius and Fallopius bestowed no acute consideration on this point, and virtually accepted the paradox (as it would seem to us) of Galen, that the thyro-arytænoid and arytenoid muscles alone acted as constrictors of the glottis, whilst the crico-thyroids, with the posterior and lateral crico-arytænoids were dilators of that passage. Fabricius, however, enters (23) with minuteness into this part of the subject, and in his exposition, in fact, does it first become intelligible how such erroneous views could be firmly maintained. Thus, granted two false premises, the whole theory of the intrinsic laryngeal movements is based on the clearest logic; first, the supposition alluded to above, that the vocal bands did not closely approximate for phonation, and hence the conclusion that the area of the *rima glottidis* would always be increased antero-posteriorly when contraction of the crico-thyroid muscle lengthened the distance between the thyroid and arytenoid cartilages; and, secondly, rotation of the arytenoid cartilages not being recognised, and horizontal rectangular notions only being allowed, the inevitable conclusion was adopted that the lateral and posterior crico-arytænoids alike acted in drawing the cartilages apart. Hence, although the last muscle is correctly reckoned as a dilator, its method of action is altogether misconceived. Although Fabricius is under the influence of these errors he yet makes an advance by surmising that some of the fibres of the lateral crico-arytænoids would be more likely to move the arytenoid cartilages towards each other. Another opinion of Fabricius deserves both mention and consideration, viz., he classed the thyro-hyoid muscle among the constrictors of the glottis and as the direct antagonist of the crico-thyroid, that is, as a dilator of the crico-thyroid space, and a rotator upwards and backwards of the thyroid cartilage. In this way he accounted for the rise of the larynx in emitting high notes, and *vice versa* for its depression in producing grave tones by combined action of the crico-thyroid and sterno-thyroid. In another suggestion Fabricius, however, makes some progress, *i.e.*, he perceived that an extra dilatation of the glottis was required in taking a full inspiration, whence he set down the actions of the larynx as three (24), namely, phonation, holding the breath, and over-dilatation of the glottis. He made the mistake, however, which probably only laryngoscopic inspection could remove, of supposing the extra dilatation was necessary in forced expiration as well as in inspiration. As regards the extrinsic muscles, he considers that in emission of acute tones the inferior constrictor of the pharynx, by pressing together the wings of the thyroid cartilage, aids materially in gaining the required constriction of the glottis.

Casseri treats very briefly the action of the laryngeal muscles, but nevertheless takes a novel view of the use of the crico-thyroid. He states (25), in fact, that he here dissents from the opinion of all other anatomists in considering that the effect of narrowing the crico-thyroid space is to make the voice more acute, by compression of the arytenoid cartilages. His conception of the question is, of course, vague, but is yet the first step in the right direction. In discussing the action of the glottis he expresses (26) very clearly the current notions which show that the vocal bands were not regarded as directly concerned in the production of sound, *e.g.*, "Since voice arises from elision of the air, and as this issues from the meatus of the glottis, at one time constricted, at another dilated, no sane person but will acknowledge this to be the province rather of the fissure and foramen of the glottis, than of its substance."

Morgagni discusses (27) at considerable length the mechanism of the larynx in deglutition and acute phonation, and is the first to attribute to the thyro-pharyngeus (inferior constrictor), stylo-pharyngeus, and thyro-staphylinus (palato-pharyngeus) their due share in this act. He also debates (28) the question as to whether the ventricles have

an influence in diversifying the tones of the voice. His conclusion is, that they are gradually constricted in the production of high tones by the combined progressive contractions of the thyro-, stylo-, and staphylo-pharyngæi.

Santorini makes no decided advance in defining the action of the laryngeal muscles. It may be mentioned, however, that he thinks the thyro-hyoid muscles, in tilting the thyroid cartilage backwards and upwards, also carry backwards the epiglottis, thus assisting in the narrowing of the glottis required for high notes.

Marin Mersenne (1588-1648), Jesuit and Professor of Philosophy at Nevers, was an industrious inquirer into the laws of sound and music. Having a great practical acquaintance with musical instruments, he was enabled to reject positively the supposition that alterations of size in the vocal canals effected change of vocal pitch. (29) Thus, he observes that according to the laws of sound generated in tubes, the length or capacity of the vocal channels would have to be doubled in order to produce the octave below any given vocal note. But such a change being a manifest impossibility, and as the human voice has a compass of two or three octaves, he demonstrated conclusively that variation of pitch was made independently of the air-passages connected with the larynx. He was also more inclined than his predecessors to take into account the vibration of the edges of the glottis in the production of sound, but his acoustic and experimental knowledge was too insufficient to allow of his solving this point. He foreshadows plainly, however, that a study of the action of musical reeds will alone give the clue to the acoustic nature of the larynx.

Antoine Ferrein (1693-1769), Professor of Anatomy, &c., at the Jardin du Roi, Paris, was the first who made acoustic experiments on the natural larynx, and by so doing he advanced the physiology of the organ more than any other investigator, not excepting Galen. He is, therefore, the founder of vocal physiology in respect of the larynx. On two important questions he threw both new and true light. (30) *First*, as to production of sound, he showed on the human larynx and that of several other animals that a close reproduction of the respective voices could be obtained by bringing the vocal bands together and blowing through the trachea from below, whether the organ were detached or in its place. At the same time, he pointed out that vibration of the vocal bands was the essential factor in generation of sound, as by touching them the sound was made to cease. Further, he remarked that intensity of voice depended on the force of the blast of air. *Secondly*, as to pitch, he proved that no alteration was gained by making differences in the width of the glottis when nearly closed, but only modification of the force of the sound; whereas, that if traction were made on the vocal bands by seizing the arytenoid cartilages with the fingers or forceps, almost any desired rise of pitch could be effected proportionately to the tension. Then he demonstrated that the function of the crico-thyroid muscle, in approximating the thyroid and cricoid cartilages, was precisely to bring about the graduated tension of the vocal bands in forming a musical scale—a fact which he ingeniously proved by the observation and discovery that if the finger be placed on the crico-thyroid space, it can be felt to close by degrees whilst the voice is raised from grave to acute tones. Further, he pointed out that the vocal bands follow the laws of vibrating strings as to the relations between pitch and length—*e.g.*, if shortened by one half or a third, their note would be elevated to the octave or sixth, &c. So far, then, these great and incontrovertible facts, though often afterwards sophistically disputed, were revealed by the experiments of Ferrein, but he also arrived at two erroneous conclusions—one on account of the deficiency of acoustical science in his time, and the other owing to the impossibility of his seeing the larynx in action during life. Thus, not understanding the acoustic nature of reed instruments, he decided that the current of air drew sound from the vocal bands, as the bow acts on the strings of the violin—a comparison which, though having some mechanical truth and good as a simile, is yet false in acoustics. Hence he regarded the edges of the glottis as being virtually strings, and called them *the vocal cords*, an improper name not yet altogether abandoned. This venial mistake has unjustly brought Ferrein into disrepute amongst modern writers who are generally acquainted only with this "string theory," which forms but a narrow appendix to his valuable labours. Ferrein's second error was that, on recognition of the fact that after closure of the crico-thyroid

space the voice could still be carried up in the falsetto register when further tension became impracticable, he ignored his own researches as to shortening, and stated that in this case a new vocal organ was formed by a peculiar contraction of the parts above the larynx.

The first anatomist who asserted the true action of the lateral crico-arytenoid muscles was Augustin Frederick Walter, an Englishman, Professor of Anatomy, &c., at Leipsic. In 1740 he stated (31) that they "drew forward the arytenoid cartilages, at the same time closing the anterior two-thirds of the glottis"—*i.e.*, the cartilaginous glottis. His demonstration, however, was received with incredulity at the time and ignored for half a century afterwards.

Willis, who elaborates his anatomical descriptions with diffuse hypotheses, thinks that the superior laryngeal nerve presides over upward movements of the larynx and trachea, as required in expiration, utterance of high notes, &c., and that the recurrens possess opposite functions, the anastomosis between the two providing for co-ordination in their action. "For the performance of this duplex motion," he remarks, "(like the hands of a pipe-player, of which one modulates the upper, the other the lower holes) two nerves are constituted—that is, the offshoots and branches of the recurrens borne from below move the cartilaginous rings downwards, and the nerve sent down from this plexus at once draws the superior rings upwards," &c. These speculations of Willis serve to show how backward the physiology of the innervation of the larynx was at this period.

*Pathology.*—In this division our attention is first engaged by a group of neo-Latin authors of uncertain date and personality, most of whom lived about the end of the thirteenth or beginning of the fourteenth centuries. Amongst these the chief names are Rolandi, of Parma; Lanfranc, of Milan; Brunus Longoburgensis, Gulielmo de Saliceto, and, latest of all, Guido de Cauliaco, who wrote in 1363. Unprogressive rather from lack of opportunity than inclination, they followed the practice of the Greeks and Arabians, relying mainly on the authority of the latter, and were the immediate progenitors of the moderns, for whose advances they paved the way by disseminating popular epitomes of their art. In these works they described the four kinds of kyanache or *equinantia*, as they termed the disease in their corrupt Latin, and sometimes related unusual personal experiences with their own judgments thereon.

In Rolandi (32) we find some practical remarks on a kind of growth in the larynx, which are doubtless the earliest definite reference to such a disease. "There is also," says he, "another affection which arises in the mouth near the epiglottis, called *folium*. One or two caruncles, thin and broad, of leaf-like form, situated round the windpipe, impede the voice, so that when the patient opens his mouth to speak they raise themselves and block the opening of the windpipe, subsiding, however, when the mouth is shut. Hence the patient is scarcely able to utter an intelligible word. The affection is never cured unless by the aid of surgery."

The medical writers of the next three centuries may also be considered collectively, as holding opinions almost identical, and of little or no originality with respect to laryngeal disease. Here, as in preceding times, but one malady of the larynx is practically taken into account, *viz.*, synanche or acute laryngitis; but, owing to the greater exactitude and familiarity of anatomical knowledge, its nature is more strictly and intelligibly defined. The principal pathological writers of this second group are Jacobus Hollerius, of Paris (flourished about 1520); Jacques Dubois, of Lyons (1478-1555), euphuistically called Sylvius, ultimately professor of medicine, &c., at Paris; Hieronymus Mercurialis (1530-1606), professor of medicine at Padua; Thomas Sydenham, of London (1624-1689), entitled the father of English medicine; with Fallopius and Fabricius already mentioned, and some others who need not be named till dealing with the treatment. The views of all these observers may be fairly summed up in a statement of Fallopius when concluding one of his chapters on the anatomy of the larynx:—"When the muscles of the larynx are inflamed a most acute angina is generated; for, when they are brought into a state of swelling, the exit of the breath is constricted on account of their large amount of substance, so that the animal is suffocated quickly." Fallopius (33) observed that hoarseness was an usual symptom in advanced syphilis (*raucedo syphilitica*), but did not go beyond the pharynx in searching for its cause.

We see, therefore, that during the greater part of this

period the advances in laryngeal pathology are scarcely appreciable, nor is it until we approach the threshold of the eighteenth century, that a decidedly wider apprehension of the subject is initiated. Michael Ettmüller (1644-1683), professor of surgery, &c., at Leipsic, appears to be better versed in this subject than his contemporaries. He makes allusion (34) to defects of voice arising from tumour of the larynx or in its vicinity; to aphonia from paralytic or convulsive lesions of the nervous muscles of the organ. He remarks that aphonia of a convulsive origin is observed "in hysterical and epileptic persons, likewise from worms." "A virgin," he states, "from inspiration of the smoke of an oil-lamp, fell into a paralysis of the larynx, with subsequent aphonia." He also mentions "a suffocative catarrh of infants, joined with an epileptiform motion, but with little or no cough." On the whole, however, his pathological conceptions, vague and obscure, do not show much practical advance beyond the somewhat similar ideas of Galen.

Hermann Boerhaave (1668-1738), professor of medicine, &c., at Leyden, the most celebrated physician of modern times, though the evidences of genius left by him to posterity do not equal those of some of his contemporaries, shows in his brief aphorisms (35) more discriminating views on disease of the larynx than any previous author. With the exception of acute laryngitis, there is little description, but yet we find clear and forcible suggestions of catarrh, abscess, cedema, cancer, paralysis, and spasm of the larynx. For example, he observes:—"Angina is oedematous, catarrhal, inflammatory, purulent, schirrous, cancerous, and convulsive." And further on:—"It occupies," amongst other parts, "the external, internal, common, or proper muscles of the larynx." And again he states:—"If the motor nerves of the organs of deglutition or respiration are prevented from exercising their functions, there arises a paralytic angina. . . . If any cause of convulsions occupies the muscles of the pharynx and larynx, a sudden suffocative angina is produced." (36)

John Fantoni (1675-1758), professor of anatomy at Turin, furnishes (37) some post-mortem descriptions of ulceration of the larynx, among which is, perhaps, the first ocular observation recorded in literature. In dissecting the body of a man he found "the arytenoid cartilages ulcerated around, and their size so increased that a very narrow passage was left in the larynx. The patient breathed with great difficulty, yet lived a long time in that state."

Gerard Van Swieten (1700-1772), pupil of and successor to Boerhaave at Leyden, afterwards Court physician at Vienna, has bound his literary existence to that of Boerhaave by throwing his own writings into the form of commentaries on the aphorisms of his master. These extensive and erudite commentaries consist of an expansion of each aphorism by logical deduction and by illustrative remarks borrowed from other writers, particularly Hippocrates and Galen. Van Swieten does not, however, appear to possess more insight into laryngeal disease than Boerhaave, and his elucidations can scarcely, therefore, be allowed to have advanced this subject. Yet he makes one statement which contains the first indication of glandular pharyngitis, laryngitis, &c., and even suggests a more than theoretical acquaintance with the affection of the mucous membrane. The following is the passage (38):—"The mucous recesses which are seated in the pharynx, oesophagus, larynx and trachea, if obstructed and swelled, may cause like disorders (to chronic angina), and at the same time, owing to their being diseased, there is a deficiency of mucus for lubricating the passages."

So far it is evident that the larynx occupied a very subservient position in pathology, and that, in fact, there was no definite and practical knowledge at all of the organ in disease. On this account, in the seventeenth century, its existence was almost ignored by the ordinary student of medicine, and it seems to have been regarded everywhere as an unnecessary refinement even to learn its anatomy and physiology. Such was the mouldering state of laryngology before the time of Morgagni, and from him we hear of it, because by his curiosity and penetration a revolution was affected. The circumstances attending (39) this remarkable event, which are fully narrated by Morgagni himself, were as follows:—"A virgin, set. 40, had long been asthmatic and affected with a weakness of voice, the cause of which was supposed to be a lung disease. She died suddenly during a violent attack of asthma, and the body was obtained for the anatomical theatre of Bologna. An autopsy was then made in which, in conformity with the conventional method of proceeding at that time (1704), the viscera of the abdomen

and chest with the contents of the cranium were subjected to a careful inspection. All those parts being found healthy, "every one," says the narrator, "was astonished who had diligently inspected the viscera, but much more so we who had dissected them. Then I demanded of Valsalva whether we should not also open the larynx, as by chance the cause of diminished voice, asthma, and death might be there hidden, for at that time the larynx was not opened in the course of public anatomy to show the horizontal glottis, ventricles, arytenoid glands, and articulations, parts which I had not yet discovered or restored. As he consented he ordered the larynx to be looked for among the parts not yet buried, and brought to me. And when I laid it open by longitudinal incision behind what we were seeking was at once manifest. For a whitish mass of ashy-looking pus, of a pultaceous character, like a cork, obstructed the cavity of the larynx far down below the glottis, and there the investing membrane of the larynx was ulcerated, as well as where it covered the nearest rings of the trachea, though to a less extent. Which facts, being demonstrated in the theatre on the last day of the anatomical course, gave great satisfaction to all present." Morgagni goes on to explain the presence of such plugs of inspissated pus or muco-pus by referring their formation to the ventricles, whence they might gradually be extruded so as to block the glottis.

After the occurrence of this emphasised case Morgagni always paid special attention to the larynx, and never failed to examine it in his post-mortem researches when there were any grounds for suspecting a morbid condition. He was enabled, therefore, subsequently to describe a number of cases in which the larynx was found to be diseased. As in these observations the pathological importance of the organ was first brought to light, and as they, in stimulating further investigation, became the foundation of modern laryngeal pathology it will be advisable to enumerate them briefly. (40)

1. In a man, set. 40, who died of low fever, along with somewhat similar appearances in some other organs, the larynx was found to be livid externally, congested internally, and swelled generally from a viscid serum in the sub-mucous tissue.
2. In a man beyond 40, affected with a hernia, who died suddenly from some intestinal spasm, the veins were distended with black blood, whilst the larynx and adjacent parts were "black, livid, and gangrenous."
3. In a man who died of hydrophobia, along with other evidences of stagnation and turgescence in the circulatory system, the larynx and contiguous organs were of a blackish-red colour, as if approaching gangrene.
4. Another case of hydrophobia in a man, set. 60: the throat lesions were almost limited to the surface of the epiglottis, which was "crisp and shrivelled."
5. In a man who was hanged the sterno-thyroid and thyro-hyoid muscles were ruptured, and the cricoid cartilage was fractured.
6. In a man, set. 55, who died of pleuro-pneumonia, there was, as well as general vascular turgescence, turgidity of the vessels in the pharynx and larynx.
7. In a man, set. 50, who suffered from pain and dysphagia without external evidence of disease, and who died apparently from suffocation, extensive "cancerous" swelling of the pharynx and larynx was found.
8. A very similar case in a young man, where, however, the tumours were ulcerated and the epiglottis perforated.
9. A fatal case of angina in a man, set. 33, where the larynx, as also the pharynx, was much inflamed, the epiglottis being considerably swollen, whilst a tumour filled with serum and stagnating blood, formed at the back of the cricoid cartilage, projected upwards higher than the arytenoid cartilage.
10. In an old man who had suffered many years with syphilis; besides pharyngeal and other lesions, the epiglottis and larynx generally were deformed with cicatrices, one of the arytenoid cartilages being dislocated.
11. A case of small-pox in which a pustule was found in the larynx.

Morgagni makes copious comments on all these cases, calculated to demonstrate forcibly their pathological importance. He further reports (41) two instances of aphonia in young women, one of which was cured by a fit of coughing provoked by an atom of foreign matter getting into the larynx whilst eating grapes. He surmised that they arose from the muscles of the larynx being "inert." (42)

Towards the close of this period cases of polypus of the larynx are first definitely described. We are told that in 1760 Köderik, of Brussels, extracted a laryngeal growth through the month. (43) A few years later Joseph Lieutaud (1708-1780), physician to Louis XVI., observed two instances (44) in making autopsies, a method of investiga-

tion to which he was ardently devoted. One case was that of a person who had suffered thirty years from asthmatic symptoms, and continually complained of an obstruction in the windpipe, which persistent efforts of coughing failed to remove. Death occurred suddenly from suffocation, and, on the body being opened, "a polypus attached to the larynx by various roots, pressing towards the glottis like a cork" was found. In the other case a boy, set. 12, died suddenly, after phthisical symptoms had long been present. At the autopsy a polypus growing from the upper part of the trachea by a pedicle, placed so that the breath would be likely to impel it against the glottis, was discovered. Lieutenant also reports the earliest instance of laryngeal phthisis that can be decidedly recognised as such. In the body of a youth who died of consumption he found, in addition to the usual pulmonary ravages, "a very foetid and foul ulcer of the larynx, with caries of the cartilages." (45) Several cases of foreign bodies in the windpipe and of ulceration in it, clearly associated with syphilis, are also due to this industrious observer.

- (36) J. Delacoste of London, author of an English translation of Boerhaave (1715), commenting on this passage mentions (p. 198) a fatal case of spasm of the glottis in a boy of seven which he had at first set down as "a cramp of the very bronchia." John Platearius of Salerno, about 1290, reports a case of "sudden squinantia" in an adult which was cured by thrusting a key down the throat. It seems to have been an instance of spasm of the glottis. (*Practica*, Venetiis, 1467, Tr. xi. c. 2.)

- (41) *Ibid.*, III., 15.
- (42) Morgagni also quotes a case from Targioni in which the epiglottis of a man had been entirely eaten away for some years without causing any marked inconvenience to the patient. (*Ibid.*, xxvii., 18). In 1700 Theophilus Bonetus, of Geneva, published a vast collection of cases, drawn from numerous authors, arranged in anatomical divisions. It is called the "Sepulchretum," and contains several instances of foreign bodies in the windpipe, with other throat cases, but no accurate observations of laryngeal diseases. Morgagni's great work, the result of more than half a century of labour, was not published till 1769; but cases of laryngeal disease described from autopsies were recorded before that date, probably through the impetus given to such researches by Morgagni in the actual course of his work. See, for example, Fantoni's "*Opuscula*," Geneve, 1733, p. 207, &c. (*Epist. ad Singetum*.)

(To be continued.)

## Clinical Records.

ST. BARTHOLOMEW'S HOSPITAL.

Case of Double Pneumonia (Right upper lobe, and left lower lobe).

Under the care of Dr. REGINALD SOUTHEY.

(Reported by Mr. ALBERT GRESSWELL, M.B. Oxon.)

MARTIN D., set. 27, by occupation a stone pavior, a well-nourished, largely-framed man, was admitted into Matthew Ward suffering from double pneumonia on May 20th, and was discharged well on June 16th. On admission his skin was dry and rough, face yellow, conjunctivæ were jaundiced, tongue dry and sticky, fauces natural, cervical glands not enlarged. Chest well shaped, and its movements shallow.

**Right Lung.**—There was dulness all over in front, and hyper-resonance behind intra-clavicular region. Fine crepitations also were heard over the front.

**Left Lung.**—Dulness all over behind, and hyper-resonance in front. Bronchial breathing over the lower axillary region, and bronchial breathing with crackling crepitations over the root.

**Heart.**—Impulse somewhat weak. Sounds clear. Marked reduplication of the second sound at the base over the second left costal interspace.

**Abdomen.**—Full. Not distended. Walls firm. Resonance tympanitic. The hepatic and splenic dulness not increased. Some wincing on pressure over the right hypochondrium.

Inguinal and axillary glands not enlarged.

Extremities, natural.

Patient said he had had pleurisy 12 years previously, and that the present complaints began May 13th, on which day he went to work at 6 a.m., feeling quite well; an hour afterwards violent shiverings set in, his vision at this time also became dim, giddiness and sickness followed by headache supervened, with severe pain in the loins. He left his work about noon and lay down, and in the evening he took some hot rum, which intensified his headache, and he then went to bed where he has been confined ever since. He continued to shiver and to vomit up to the time of admission, and he has eaten nothing since the onset, but has been very thirsty. He has had a painful cough, raising a red and also a deeply green sputum. His bowels were open only three times from the time of the onset to the time of admission, each time with difficulty, and the last time on the 17th inst., the motions were not light coloured, nor did they contain blood. He has not suffered from piles. Micturition has been frequent, and though he had not been accustomed to passing water nocturnally, he now did so three times every night, accompanied by pain in the lower part of the abdomen. Respirations 44, shallow; deep respirations being attended by some pain referred to the sternum. Pulse 136, bounding and soft. Temperature 103.8. Urine sp. g. 1015, containing a trace of albumen; acid deeply yellow in colour and containing also granular casts.

Ordered—D.L. Milk Oij., Brandy ʒij.

Hausustus Sod. tart. efferv.;—4tis horis.

The following daily notes record his progress while in the hospital:—

May 21st.—Very restless night. Drinks very freely of milk. Bowels not open. Respirations 39. Pulse 90, very irregular and markedly dicrotic. Tongue dry and cracked transversely.

Ordered.—Brandy, ʒvj;

Hst. sodæ tart. efferv., p.r.n.;

Sp. Chloroformi, ʒxx;

Ammon. carb., gr. iv.

Aq. menth. pip., ʒj. ter die.

22nd.—Very restless night. Wandering greatly in mind. Tongue moister this morning, but thickly covered with a brown fur all over the dorsum. Bowels not open. Takes plenty of milk. Conjunctivæ more jaundiced. Pulse 120, rather stronger, but still somewhat irregular. Ordered—Effervescing Carlsbad salts, ʒj.; in warm or cold water. Bis terre di si opus sit.

23rd.—Very restless and delirious through the night, tossing about, and at times attempting to get out of bed. Very thirsty. Tongue moister, but thickly furred over the greater portion of the dorsum with a brown, sticky coating. Perspired this morning, but skin is now quite dry. Pulse 126, rather stronger, and no longer irregular. Bowels not open. Bronchial breathing, with many crepitations, as on admission, over the left lung. Also bronchial breathing, somewhat marked by fine crepitations, over the right lung in front.

24th.—Very restless night. Got out of bed several times; delirious. Tongue still covered with a thick, brown, sticky coating. Sputa somewhat rusty, and at times very deeply green, but not so viscid. Pulse 132, regular, still soft, but the character of yesterday is maintained. Respirations 32. Bowels open freely.

25th.—Much better night than heretofore, but passed with some amount of delirium. He slept three or four hours. Perspired freely early this morning, and still is perspiring. Yellowness of conjunctivæ less marked. Pulse 132, somewhat softer, but still of fair volume. Respirations 36. Ordered—Eggs iij.; hst. ætheris, c p.r.n.; hst. morphisæ et hst. ætheris c ʒʒ ʒss. hœc nocte.

26th.—Slept a little, and early this morning he commenced to perspire, and has been still perspiring most freely. Very thirsty. Temperature fell from 103.6 last night at 8 p.m. to

## Special Articles.

### THE ARMY MEDICAL DEPARTMENT REPORT FOR THE YEAR 1883.

THE Report of the Army Medical Department for 1883, just issued, contains, as usual, a great deal of statistical information in reference to the British soldier, some of which, indeed, is, perhaps, more minute than useful. For the most part the letter-press is simply a repetition of particulars given in the statistical tables, to which are added abstracts of reports on the "sanitary conditions," in other words, the state of drainage, cleanliness, and water supply of particular stations and barracks. According to a general abstract given at page 2 of the Report, the following ratio to 1,000 strength throughout the whole army at home and abroad occurred in that year, viz., admitted 1,022; died 957; invalided 37. Of the troops in Egypt, the corresponding numbers were respectively 1,139; 34; and 84; equal to a total loss of 118 per 1,000 per annum by sickness alone; and irrespective of killed in action, and discharged for various reasons, non-medical in their nature. In June of that year cholera broke out at Damietta; in the course of the epidemic, which continued to rage more or less continuously till the end of August, there occurred 183 admissions by the disease among the troops. The type was described as having been severe, but it is particularly noted that "there was no unusual or special symptom noticed in the epidemic." This being the case we are startled to observe that of the cases above noted, the deaths mounted to 139, that is to a ratio of 70 per cent. of the admitted. It is evident that modern medicine is little, if at all, capable of combating this fearful disease, the rate of mortality of which in India whenever it exceeds one in three is considered remarkably high.

According to the table at page 83, the rates of sickness, mortality, and invaliding of the British forces serving in the Bengal Presidency in the year 1882, were respectively 1,314; 12; and 32; equal to a total rate of wear and tear by disease equal to 44 per 1,000 mean strength. By reference to the abstract given at page 205 the incidence of death and non-efficiency by invaliding in the several classes of men who make up a battalion is shown, and the results are somewhat remarkable. For example, whereas the rates of death per 1,000 were 23 in officers, and 12 in non-commissioned officers, they were only 11 in the rank and file; the invaliding in these classes being respectively 41, 25, and 31, equal to a total rate of wear and tear in that year of 64 per 1,000 in officers, 37 in non-commissioned officers, and 42 in rank and file. In other words, the rate of death among officers in 1883 was more than double what it was among common soldiers; that of invaliding nearly one-third greater. Nor are these proportions materially affected by the comparative statistics for the previous ten years given in the same abstract. If now we turn to the abstract given at page 264, we find that there is no apparent accord between the rates of deaths and of invaliding at particular stations and in particular bodies of troops. For instance, mortality was small, sick non-efficiency by invaliding was large in the 1st Dragoon Guards at Meerut; 6th Dragoon Guards at Sealcote; Royal Artillery at Peshawur; Bareilly and Mooltan, Infantry at Fort William, and Rourkee. The death-rate was large at the same time that invaliding was small in the Royal Artillery at Ferozepore, Infantry at Benares, Nurshera, Bareilly and Rourkee. Both the death and invaliding rates were large at several stations, as in the Royal Artillery at Rawul, Pindee, Fort Lahore (particularly high), Fort Attock, while, as if to bring the circumstance into more permanent relief, no similar discrepancy occurred among the infantry.

These circumstances naturally suggest various questions, to none of which, do any particulars which appear in the report before us suggest an answer. How does it happen that officers who have the means of living more completely under what are called hygienic conditions than the soldiers, whose surroundings are in all respects cleanly, whose food and whose drinks are of the best quality obtainable on the spot, and who, moreover, are not called upon to do sentry duty in all times and seasons as are the rank and file, nevertheless, die and are invalided in greater proportion than the latter? Sanitary science of itself does not give the required reply. In the second place, what explanation are we

97-6 this morning at 8 a.m. Breathing more easily, not so shallow, 30 per minute. Pulse 88, very soft, and of smaller volume. Drinks freely. Tongue moist, but still covered with a thick white fur. Bowels not open. Scarcely any bronchial quality of breathing-sounds over the right lung, but numerous fine crepitations over the front. Bronchial breathing still over the left lung root; numerous fine crepitations over the left lung behind below the spine of scapula, and over the left lower axillary region.

27th.—Good night. Feels stiff in the joints of the legs, and some stiffness all over. Pulse 90; respirations 30. Skin since last morning has been very moist.

28th.—Good night. Stiffness of legs has gone off. Skin is dry; pulse stronger, 96. A few crepitations over right lung in front, and left lung behind at base. Ordered—D. L. milk Oij.; brandy ʒij.; eggs ij.

29th, 30th, 31st.—Very good nights. Pulse 94, stronger, but smaller. Respirations 24. Skin dry, and much less yellow than previously. Conjunctivæ also much less yellow. Raises a little sputum, containing red streaks and no longer green. Creaking over left lower axillary region. Ordered D. D., milk Oij.; pudding, eggs ij.

June 1st and 2nd.—Very good nights. Takes well. Pulse 88; respirations 22. No abnormal physical signs in lungs.

3rd.—Very good night. Takes well. Bowels not open. Pulse 82; respirations 24. Ordered—Hst. quin. c. pot. i. d. t. d.; pil. coloc. c. and pil. rhei c. ʒʒ, grs. v., hōc nocte.

4th.—Doing well. Pulse 78, stronger and fuller. Respirations 24. Yellowness of skin and conjunctivæ has almost disappeared.

5th.—Very good night. Takes well. Bowels open once. Urine contains *no albumen*. Pulse 72; respirations 24. Ordered—D. C. milk, pudding, beef-tea; and hst. quinæ c. pot. i. d. t. d. The patient continued steadily to progress till June 16th, when he was discharged well. He took with him hst. quin. c. pot. i. d. (sufficient for seven days).

*Remarks.*—The jaundice of the patient seems to have been of recent origin, and indeed was part of his illness. His account to the effect that he had noticed a yellowness of the skin for four weeks, but had not noticed a yellowness of the conjunctivæ until the day of admission seems to be inconsistent, for jaundice is generally noticed in the conjunctivæ earlier than in the skin. His jaundice may be attributed to the pyrexia, for jaundice is said to accompany marked pyrexia; or, with show of probability, it may be attributed to a diaphragmatic pleurisy, which is frequently attended by some degree of jaundice. The markedly green colour of the sputum may have been perhaps due to the same cause as the general sallowness, and the yellowness of the conjunctivæ. As regards the administration of stimulants. The patient's pulse was very soft on admission, and his tongue very dry; stimulants were therefore ordered. On the following day the stimulants were increased, and a favourable effect seems to have followed, for next morning his tongue was moister and his pulse not so compressible. He distinctly "stood" the stimulation well; he indeed was better, and the *post hoc* was thought to be *propter hoc*, therefore the stimulants were continued. The patient took his effervescing mixture with great eagerness; he said it refreshed him considerably, and left him more inclined to take of nutriment. The disease ended critically, i.e., the temperature fell suddenly, and the fall was accompanied by a profuse perspiration. Such an ending is almost always favourable and justifies a happy prognosis, and certainly all the cases of lobar pneumonia which have been marked by a crisis in Dr. Southey's wards during the last year did well after the crisis. I may perhaps except one case, a boy in "Matthew," whose temperature fell by crisis, and remained low for some days, and then suddenly rose to a great height. This, however, was apparently owing to being severely frightened by a patient in the next bed, who was suffering from delirium tremens. The temperature of this boy varied for some days, oscillating up and down after the fright.

M. STRAUS finds that the proportion of tuberculous calves does not reach 1 in 100,000. So the danger of tuberculosis in obtaining vaccine from these animals is practically nil.

to have for the circumstance brought to light, that the incidence of death and invaliding is not necessarily in accord at the stations indicated? In these days when it is more or less the custom to look upon disease as being a specific entity, rather than as a condition, how are we to explain the circumstance indicated by that theory? No reply presents itself.

Still adhering to the statistics of the troops in the Bengal Presidency, we refer to the abstract given at page 192. Of continued fevers, in a strength of 34,395 men there occurred 4,001 cases and 88 deaths, of which number 274 admissions and 84 deaths were by enteric. Paroxysmal fevers being grouped together it becomes impossible to separate cases of severe remittent, from those of ordinary attacks of ague, which come and go without especial risk to the life of the patient. Taking the group however, as given in the statistical Returns, including as it does, dissimilar elements, there occurred 12,756 admissions by paroxysmal fever, and in that number 14 deaths. Taking the cases returned as enteric, the statistics show that the rate of mortality by that fever was nearly one in three of those attacked, while that of other forms of continued fever was little over one case per thousand. How is this? Was treatment futile in the one, and remarkably successful in the other form of fever? Some cases that proved fatal, and those that assumed severe types of fever returned as enteric, those less severe as continued. The Returns give no information on either of these points.

Comparing the prevalence of enteric fever in 1883 and in previous years (p. 86), an increase was shown to have occurred, whereas, according to the theory of its etiology, a decrease should have been shown to correspond with the continued progress of "sanitation." As though the disease was more or less prevalent throughout the year, the greatest prevalence occurred in the second and third quarters, that is, during the hot and rainy seasons. This circumstance is not to be accounted for on the zymotic, although it readily is so on the climatic theory of the disease, conditions of conservancy were alike at all seasons, but the general conditions which constitute climate varied, and so did the prevalence of "enteric" fever. At Lucknow also (p. 86) "35 attacks and 7 deaths occurred in the Derbyshire Regiment, which had arrived in India from Egypt in November, 1882, and was composed principally of very young soldiers. The source of the disease could not be ascertained, the sanitary condition of the barracks was excellent." Why! the source of the disease is plainly indicated in the paragraph quoted, namely, the fact of a number of young soldiers being exposed to a hot and rainy season in India. But preconceived theory has led to that circumstance being altogether overlooked, to inquiries being limited to only one series of conditions, and now these cannot be found, as in India they never can, to a wall that "the source of the disease cannot be ascertained. With regard to the remarks on this head contained in the Reports before us, they furnish a striking example of how, in order to support a theory popular at the times, facts are constrained and interpreted in a particular way. With regard to treatment pursued in cases of illness these Reports contain very scanty information, and yet, surely it is of importance that they should contain full particulars on this, the chief subject to which the attention of the Army Medical officer can be directed.

## The Annual Meeting

OF THE

## BRITISH MEDICAL ASSOCIATION.

THE second visit of the Association to South Wales, after a lapse of twenty-two years, may be taken to have been one of more than average success. The locality selected for the meeting, though not specially interesting in itself, was within reach of many scenic attractions, and as Cardiff is in the highest degree a centre of prosperous and active business all that money could do to make the visit of the Association a successful one was done. While the members of the profession who were its host on this occasion made it

manifest that no effort of theirs had been spared which could add to the enjoyment of their guests. We cannot, indeed, speak too warmly of the enthusiasm displayed by the President and Local Committee who performed their duty as entertainers not only with warm-heartedness and liberality, but with a degree of administrative ability which ensured for the entertainments, which they arranged, a complete success, and deserved the sincere acknowledgements of those who partook of their hospitality.

The attendance of members was not as large as usual, a fact which arose, we imagine, from the length and intricacy of the railway approaches of Cardiff from the North of England, and from Scotland and Ireland. Five hundred and sixty members had previously notified their intention to be present, of whom Scotland was represented by 14, and Ireland by 20 members. The usual continental, colonial, and foreign visitors were not as numerous as usual.

### THE FIRST GENERAL MEETING.

The opening general meeting which took place on Tuesday at half-past three was a very full one, much interest being excited by some of the propositions contained in the Report of the Council.

In issuing their first report under the new constitution the Council expressed a hope that the Association might be as successfully governed in the future as in the past. The new constitution, by placing the whole policy and management of the Association under the direct control of the members is, they venture to think, more adapted than the old to its increased wealth and numerical importance.

To this proposition every member of the Association would enthusiastically assent if it were true in fact as it is in theory, but unfortunately it appears, for reasons to which we shall presently refer, that the practical realisation of the intention of the new constitution exists at present entirely in the imagination of the Council, the "policy and management" of the Association being in no important respect altered from what it was under the old constitution. The roll of members show an increase of 423 new names during the year past, raising the entire strength of the Association to the very handsome total of 11,249. The distribution of the constituency of the Association is worthy of notice. The London and the Lancashire and Cheshire districts contribute over 900 members each, and the south-eastern district nearly 500 members, while all Ireland produces but 499 (of whom 250 are from Belfast), and Scotland but 340 members.

The revenue of the Association for the past year was £22,256. The expenditure, inclusive of losses, amounted to £19,937, leaving a surplus of £2,319, which raises the total invested funds of the Association, exclusive of trust funds, to £19,541.

### A NEW PRINTING-OFFICE AND CLUB.

Being in possession of this handsome reserve fund, the Council has forthwith proceeded to get rid of it by purchasing, at a cost of £15,000, a new site for printing offices and for buildings which will serve the purpose of a metropolitan club for the members, and they propose, we believe, to expend £10,000 more on the necessary buildings. It was this proposal which brought the members together at the general meeting, and it was hotly resisted by Dr. Dix and Dr. Bampton, the representatives respectively of the Hull and Plymouth branches, who maintained, firstly, that it was unnecessary and inexpedient for the Association to engage in the risks and responsibilities of a large printing establishment; and, secondly, that while it was highly desirable that

a suitable London club-house should be provided for the Association, it was quite unnecessary and unwise to expend £15,000 in the purchase of a site in the Strand—the most expensive part of London, and a position by no means suitable for a club.

The advocates of this expenditure acted with great discretion in mixing up the propriety of establishing an Association Club with the controversy as to the speculation in printing—for to the former proposition there was no opposition, and the printing office scheme was thus carried through without difficulty. There can be no question that the Association has reached a period of its history at which it should have a local habitation creditable to its influence, and, inasmuch there is no pressing demand for money for other purposes, it may be justifiable to expend the entire accumulated funds on such a club. These funds, if judiciously invested in buildings, will be locked up but not lost, and it is perhaps as well that they should be thus protected from the danger of expending them for ephemeral purposes.

The printing speculation is another affair, and respecting it we have only to say that, assuming that the financial and commercial results of it have been thoroughly thrashed out by competent accountants and persons experienced in printing, and assuming that a substantial saving in the cost of production of the *Journal* is to be expected, the speculation is justified. We must believe that the matter has been fully inquired into, and those who so believe ought to approve of the speculation. But if this thing were to be done upon any other grounds, the Association should unhesitatingly condemn the expenditure.

The arguments put forward by some of the Council speakers were simply puerile and calculated to create the doubts which they were intended to remove.

Eventually, the recommendation of the Council that this expenditure should be made passed by a large majority in the following terms:—"That the Council authorise the Sub-committee to continue its labours, and to offer a sum, not under any circumstances to exceed £15,000, for a freehold site, or £800 a year for a leasehold site of not less than 80 years, and that before concluding any bargain the Sub-committee report to a meeting of the Council."

#### ADMISSION OF HOMŒOPATHS.

The question of retaining homœopaths as members of the Association is reported on as follows:—"The Council have had under their consideration the subject of admission and retention of homœopaths as members of the Association during the past year. An inquiry has been made throughout the thirty-three branches, and the result has been that there is evidence to the effect that a large majority of the members are adverse to the admission of homœopaths as members, but an equally large proportion are opposed to the idea of the expulsion of those members who have already gained admission into the ranks of the Association. Your Council, therefore, feel that this decided expression of opinion by the branches should guide the future action of the Association."

While we fully approve the suggestion that the Association should abstain from making martyrs of the homœopaths by expelling them, we regret very much that the Council did not offer some suggestion more satisfying than the naked proposition that "this expression of opinion should decide the future action of the Association," a method of dealing with the subject which indicates a great want of nerve power in the Council. It has been ascertained

beyond doubt that the Association at large objects to the admission of homœopaths, and yet no rule is proposed which shall, in the future, afford protection against such intrusion. Any branch may, without hesitation, set at nought this very mild "expression of opinion," and may send forward the name of a homœopath for membership, and, he being admitted by the Central Council in ignorance of his character, may retain his membership without breach of any rule whatever. It seems obvious that the Council has no active desire to give binding effect to the determination of the Association in this matter, and it will be necessary to re-open the question on the first occasion with a view to the enactment of a rule which will for ever set the matter at rest.

#### THE REPRESENTATION OF THE BRANCHES IN THE CENTRAL COUNCIL.

The proposals for facilitating the attendance of the representatives of branches at the Central Council Meeting, with which most of the members are probably familiar, are—*a.* That of Mr. Dix, that the branches shall pay the railway expenses of such members, and *b.* That the branches shall be at liberty to appoint as their representatives persons resident not within the district of the branch, but somewhere within easy access of London. The former of these proposals did not meet with general approval, and for obvious reasons, *firstly*—because, the railway fare is but a small fraction of the sacrifice which a representative makes in going to London, and its repayment to him would not, therefore, in any great degree facilitate his attendance. *Secondly*—That if he were a man whose time were of little value, and who could ill afford to pay his way, it would be better to send someone else, and if he were engaged in a lucrative practice and, nevertheless, willing to sacrifice his time and his fees, the payment of his railway fare would not be desired by him. Mr. Brown's proposal to allow branches to appoint representatives resident in or near London was quite unexceptionable, and ought to have been at once accepted.

It would, in no way, deter a branch from appointing a local man if they could get one willing to serve, while it would ensure representation of those branches which could not find such a man amongst its members. The logic of some of the Council opponents of this proposition was quite ludicrous. One senile exponent of the Council's policy objected to the payment of the rail-fare of a man from Cardiff, because it would not be possible to pay the rail-fare of a man from Jamaica, and he further objected that a London man must necessarily misrepresent a provincial branch being, apparently, unable to understand that a misrepresented branch could meet that objection by removing him at the end of the year,

The proposal was, of course, outvoted by the Council.

#### THE POLITICAL HELPLESSNESS OF THE ASSOCIATION.

The motion of Dr. Jacob, which asked the Council to organise the political influence of the Association at the coming General Election, in order to advance medical interests in Parliament, irrespective of all political or sectarian considerations whatsoever, was dealt with in a way which was most discreditable to the Council, and which has made clearly manifest the determination of that body to crush out every proposition which does not emanate from itself, no matter whether the Association at large approves of it or not. Dr. Jacob moved this resolution, and it received such support from the meeting that the President stated from the chair that the members being apparently unanimous in its favour, he would put the question to a vote

without hearing speakers (of whom there were several) in support of it. When he was about to do so, the Editor of the *Journal* stood up and gave the cue to the councillors present to leave the room, in order that the motion might be counted out, and this hint, being backed up by the chairman of the Medical Reform Committee, the Council left their seats in a body, and the Editor then moved that the meeting be counted out, which was accordingly done. The Editor and his following have, no doubt, congratulated themselves on having by this smart, but not very reputable, trick defeated the intention of the members of the Association, and prevented any inconvenient questions being asked of would-be M.P.s as to their views on certain burning affairs—especially as to their alliance with the syphilis-propagation associations. But it will be as well to recollect that it is scarcely wise for them to display so publicly their disposition to maintain the despotism of the *coterie* who now lead the Association by the nose. A count-out trick of this sort does not protect them from the necessity of facing the question on another occasion, but, on the contrary, prevents them meeting it with *clean hands*.

#### THE ADDRESSES AND THE SECTIONAL WORK.

With the exception of the inaugural address of Dr. Edwards, the President, the public orations delivered at the general meetings were things to be read, not heard. Brevity was not their characteristic, nor was their method of delivery calculated to grasp the attention of the auditors. In fact, notwithstanding that they were delivered by men of the highest repute and excellent in material, they were exceedingly dull. To this, as we have said, the President's was an exception, because it dealt with a variety of subjects, and was concise and explicit. Dr. Roberts, of Manchester, gave the address on Therapeutics, taking as his subject "The Feeding of the Sick," and Dr. Jones Dyke, of Merthyr Tydvil, devoted his Public Health Address to the sanitary statistics of that town, Dr. Wilks's address on Medicine treated on the "Causes of Disease, and Reparative and Destructive Processes."

Of the contents of the museum and the entertainments provided for the amusement of the members of the Association we cannot now speak as fully as they deserve, and we shall therefore reserve them as the subject of our sketch of the meeting next week.

#### POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

The annual meeting of this Association was held in the lecture room of the public hall. Dr. Joseph Rogers, the chairman, presided. The President's address was in the main a review of questions and disputes that had arisen during the year affecting the action of poor-law unions towards medical officers. In regard to the Lunacy Act Amendment Bill, the President particularly quoted Section 5, which provides that an order for the admission of a lunatic into a workhouse should be made on the application of the relieving officer, supported by a certificate under the hand of a duly qualified medical officer, not being an officer of the workhouse, and by the certificate of the medical officer of the workhouse. This provision should be resisted on the ground that it was a gratuitous affront to, and a reflection on, the medical officer, who was to have the care and custody of the lunatic for fourteen days or more. On the whole, the council felt that the Bill was framed in the harshest, and most unjust, and most ungenerous spirit towards workhouse medical officers, and called on such officers to prevent Clause 10 and Sections 1 to 7 becoming law. The honorary secretary (Dr. J. W. Barnes) stated in his report that the

membership was increasing, and great interest had been taken by the members in the work of the association. They were also financially in a better state, having about £40 or £50 to the good. They still found medical officers holding aloof, however. One reason was, doubtless, the fear that they might be brought into conflict with the guardians through the interference of the Association. It should be understood, in answer to such a fear, that the Association would never dream of taking up a case without the consent of the medical officer. Alluding to the Bill for the disqualification of medical relief, Mr. Barnes denounced it as retrograde, and as one of repression of Poor-law medical officers. Votes of thanks were passed to the conductors of the *Lancet* and of the *British Medical Journal*, and to the President for his instructive address, as well as for the interest he showed in the objects of the Association.

#### THE IRISH GRADUATES ASSOCIATION.

The Irish Graduates Association held its annual meeting at 12.30 on Wednesday at Cardiff, the chair being occupied by Dr. Waters, of Chester, ex-President, the President, Professor Stokes, being unavoidably absent. The nomination by the Council of Dr. Macnaughton Jones as President for the ensuing year was unanimously adopted by the Association. The report noted a large increase of membership from 132 to 257, and expressed the hope that before long it might be possible to provide rooms in London for the meetings of the members. It also suggested that the number of stated meetings should be three instead of two annually, the chief of which is to be held on St. Patrick's Day. Professor Balthazar Foster, of Birmingham, had been compelled by the increase of his public engagements to decline the Presidency, and to withdraw from the Chairmanship of the Council. The financial report, showing a satisfactory increase in the cash balance in the hands of the treasurer, was presented and adopted. A revised code of rules of the Association were read from the chair, and after some amendment were adopted as the future law of the Association. A vote of thanks to the secretaries and treasurer was warmly adopted.

**The Mortality of Foreign Cities.**—The annual death-rates per 1,000 in the principal foreign cities, according to the last weekly returns communicated to the Registrar-General, are as follow:—Calcutta 17, Bombay 26, Madras 31, Paris 20, Geneva 16, Brussels 23, Amsterdam 22, Rotterdam 22, The Hague 19, Copenhagen 17, Stockholm 18, Christiania 26, St. Petersburg 29, Berlin 35, Hamburg 25, Dresden 21, Breslau 45, Munich 38, Vienna 28, Prague 33, Buda-Pesth 31, Rome 21, Turin 25, Venice 26, New York 26, Brooklyn 25, Philadelphia 22, and Baltimore 20.

**Vital Statistics.**—The deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 19.5 per 1,000 of their population, and were—Birkenhead 15, Birmingham 16, Blackburn 18, Bolton 11, Bradford 16, Brighton 9, Bristol 13, Cardiff 19, Derby 14, Dublin 19, Edinburgh 14, Glasgow 24, Halifax 18, Huddersfield 18, Hull 14, Leeds 16, Leicester 36, Liverpool 21, London 20, Manchester 24, Newcastle-on-Tyne 26, Norwich 10, Nottingham 17, Oldham 15, Plymouth 16, Portsmouth 14, Preston 27, Salford 18, Sheffield 17, Sunderland 21, Wolverhampton 11. The highest annual death-rates from diseases of the zymotic class in these towns were—From measles, 2.3 in Manchester and 3.7 in Newcastle-upon-Tyne; from whooping-cough, 1.6 in Preston and 1.7 in Birkenhead; from scarlet fever, 1.0 in Newcastle-upon-Tyne and in Preston, and 1.4 in Leeds; and from diarrhoea, 3.6 in London and in Preston, and 18.4 in Leicester. The deaths from diphtheria were 19 in London, and but 9 in the thirty other towns. Small-pox caused 14 deaths in London and its outer ring and 1 in Liverpool.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 5, 1885.

### THE INFLUENCE OF ENVIRONMENT ON DISEASE.

THERE is a growing tendency in the profession to regard the annual meeting of the British Medical Association more in the light of a pleasant social *réunion* than as a strictly scientifically inclined gathering, and it must be confessed that there is a good deal to lend support to such an opinion. Consequently also on the distinctly pleasure seeking nature of the excursions, a tone in harmony with its aims is observable in many of the addresses that are delivered in connection with it; and it is no slight tribute of praise to record that the two-fold object of instruction and entertainment is often very successfully secured in the compositions in question. At the meeting which was brought to a close at Cardiff last Saturday many papers were read which can justly claim to be regarded as excellent; and we would especially mention the Address on Medicine prepared by Dr. Wilks. Its learned author does not claim for it, nor would he be pleased to hear the assertion made, that it is suggestive of any new thing; but it is much in these days to have presented to us familiar thoughts in such guise that they must give cause for renewed reflection on subjects familiarised by long acquaintance.

The influence exerted by the environment on the

physiological life of the individual is, at all times, a fascinating subject of study, and it is likely ever to remain a productive field of observation for all philosophic practitioners of medicine, leading constantly to new and valuable observations of the relations between cause and effect. The circumstances of surroundings must of necessity be undergoing constant changes and ever-varying alterations as the progress of civilisation outdo the elementary novelty in the social life of nations; and inasmuch as the delicate organism of science is framed to react to each strange influence which, when oft repeated, grows into custom, so will there be presented to the physician an unending series of bodily indications of the working of such influences, with a corresponding succession of phenomena bearing with more or less directness on the production of healthful and on pathological processes. It is wisdom that suggests the importance of viewing every fresh "discovery" from such a standpoint as is shadowed forth in these reflections; and it is wise to bound the speculative instinct within the limits that experience has proved to be judicious, not permitting fancy to carry us a further distance than can be retraced when a check arrives to overthrow the calculations based upon data which have been accepted as fixed without their being sufficiently confirmed in fact. The illustration to this end afforded by the history of the bacillus controversy, to which Dr. Wilks adverted is very apt to the occasion. There has been, and there still is, danger of too rapid formation of conclusion in this connection, and while still we are not certain of the final halting place to which science is conveying us, it is well to maintain a retrospective attitude lest the rush of conviction should carry us beyond the limits of safety in regard to the treatment of those afflicted with pulmonary disease.

The Address to which we have referred is admirably calculated to serve the purpose it was designed to meet; without introducing abstruse problems of physic it provokes reflection on the principles that underlie disease, and it offers an impressive caution against too enthusiastic adoption of theories which still await the movements of extended observation and experience to lend them weight. We can afford to listen to many such instructive essays, and we shall never act injudiciously by accepting them as guides in thought and in action.

### FEEDING THE SICK.

It is often—we might even say always—a matter of wonder to commencing practitioners of medicine that no specific instruction has been given to them while students on the subject of sick-room dietetics. At once when they enter on the practical duties of professional life they find themselves called upon to answer the question, probably put by their first patients, "And now, Doctor, what shall I eat?" The young physician needs no reflection to convince him that the inquiry is not merely a natural one, but that it is in a majority of instances a supremely important one, and that on the manner in which he answers it the well-doing of his patient will principally depend. Then it is that he looks back on the long course of his studies, and strives in vain to recall that he has

ever received any systematic information in this essential department of physic. Scattered observations, and occasional descriptions of the kind of food appropriate for particular cases of disease he will probably remember to have heard during the course of a clinical lecture, or falling from the lips of the physician during his visits to the wards; but such fugitive utterances are, he feels, in the hour of need, of small service to extricate him from the difficulties of his situation, and he consequently is compelled to fall back on the limited resources of his recollection in order to satisfy the anxious demand of his client for instruction in the way of eating and drinking.

The present system of teaching medicine is in this respect sadly deficient; and whether the cause is to be found in a misappreciation of the importance of the subject, or in a want of adequately informed instructors, it is one that calls for early remedy. And this is the more necessary since the public is rapidly becoming more or less acquainted with the principles of nursing, and thus in a position to criticise the shortcomings of medical attendants in the same direction, so that it behoves the profession to be alive to the possible loss of esteem that may be occasioned by the ignorance of commencing practitioners on the subject of sick-room diet. Fortunately, however, there is the appearance of awakening to the necessities of the hour on the part of at least a few of those who are in the present ranks of teachers; and most of all are we indebted to Dr. W. Roberts, of Manchester, for both exposing the truth and for showing the manner in which the faults of the past may be remedied in the future. Dr. Roberts communicated one of the most important papers read at the Association meeting at Cardiff last week to the Section of Medicine on "Feeding the Sick." In this admirable address Dr. Roberts has given in outline a vast amount of information, armed with which the practitioner need not fear embarrassment when met with a request for directions as to the feeding of his patient. It was not of course possible in a single communication to embody all that can be said with advantage on so large a subject; but the principles expounded and the details as to forms of food to be administered together constitute a solid and invaluable contribution to practical therapeutical science, and an unquestionably serviceable guide to the general practitioner.

Dr. Roberts' teachings, however, will we trust, have a more widely extended effect than that of assisting the efforts made by those who immediately profit by them. Though we have not yet in our great schools of medicine any systematic instruction on the subject we are discussing, it is by no means improbable that it will ere long obtain a recognised position in the curriculum. Indeed, if the doctor is to hold his own, it must be so, for the haphazard education he receives now-a-days in the science of dietetics is the prime cause of the disagreements among physicians in their advice to patients on the question of food and drink, and of which the public justly complain. Dietetics is a most important branch of therapeutics, and as such it must henceforth be recognised.

THE Baly Medal presented by the Royal College of Physicians of London has this week been awarded to Mr W Kitchen Parker, F.R.S.

## Notes on Current Topics.

### Metropolitan Hospital Sunday Fund.

THE Council of the Hospital Sunday Fund met at the Mansion House on Friday last to receive the report of the Committee of Distribution. Sir Sydney Waterlow, M.P., in the absence of the Lord Mayor, presided. The awards recommended included 154 institutions, being an increase of six over last year, and of forty-nine since the awards were made in 1873. After allowing for liabilities and the usual current expenses, the amount available for distribution was £33,444, and of this total £32,084 was recommended to 101 hospitals and 53 dispensaries. On the motion for the adoption of the report, the Rev. Dr. Allon called attention to the fact that in the University College Hospital only those who were members of the Church of England were admitted as probationers for the nursing, which was thus in the hands of one sect, while the University College Hospital participated in a fund to which the members of all churches and persons of all creeds contributed. He moved that the amount of this year's award (£1,293 15s.) should be withheld from University College Hospital until it made nursing arrangements satisfactory to the Council. He was afraid that, unless this question was satisfactorily settled, half the Nonconformists of London would secede from the fund.—The Rev. R. J. Simpson coincided with the views of Dr. Allon, and seconded his motion, but thought they could not withdraw this year, as the award had been made. After some further discussion, in which Mr. Kitto, Mr. Christie, and others took part, Dr. Allon accepted a suggestion of the Chairman, that he should put his motion in the following form:—"That no further grant be made to University College Hospital until the General Purposes Committee of the Fund have fully considered the correspondence in reference to the system of nursing complained of, and reported thereon to the Council." To this it was proposed to add the words—"and have also reported whether any other institution receiving awards from the Hospital Sunday Fund is nursed upon a system similar to that adopted in University College Hospital."

The establishment of the Hospital Sunday Fund has undoubtedly brought the general public into closer contact and sympathy with hospital life, but this possibly has its drawbacks as well as its advantages. The discussion which has taken place with regard to the nursing of University College Hospital seems to support this view. The complainant in the first instance with regard to the nursing was probably unaware of the fact that the hospital and the sisterhood which has for so many years done the nursing are two perfectly distinct institutions. The authorities of the hospital pay for and expect to be well nursed; they know nothing of, and have in fact nothing to do with, any of the rules laid down by the sisterhood for those who desire to join its nursing staff. The hospital has to do with the cure of the patients admitted to its wards; and we all know how much good nursing assists in the attainment of this object. The Anglican Sisterhood has carried out its work and duties to the satisfaction of every one connected with the hospital, and we think the Hospital Sunday

Fund could not with any show of honesty have withheld the grant recommended by its own Committee. We quite agree with our contemporary the *Spectator* that "it seems to us that for such a work as nursing an *esprit de corps* founded on a religious creed is far better than an *esprit de corps* founded solely on the desire to relieve suffering, and much better than no *esprit de corps* at all." To carry Dr. Allon's argument to its legitimate conclusion must lead to the employment of those without any creed at all. Agnosticism is as good as anything else to some people.

#### The Testimonial to Dr. Bradley.

WE are glad to see that the movement initiated by us in favour of Dr. Bradley, of Brimington, is gaining strength. If the legal decision in this case had remained unchallenged the safety of every medical practitioner would be assailed. We owe it to Sir W. Harcourt that this decision has not been reversed. But to prevent a moral reversal by public opinion even Sir W. Harcourt is powerless. A very influential meeting was held at Cardiff on Thursday last, when resolutions were passed sympathising with the unfortunate victim, and binding the meeting to raise a fund in his favour. Considerable sums have been already promised, and among the first announced on the spot were £10 10s. by Mr. Marston Buzzard, Q.C., M.P., who defended Mr. Bradley on his trial, and is, therefore, more conversant with the case than any outsider, feels very strongly on the subject; Sir W. Jenner, Bart., M.D., £10 10s.; Mr. Lawson Tait, £10 10s.; Editor of the *Medical Press*, £3 3s.; &c.

Having from the first taken a lively interest in the case, and personally, and by deputy, presented the case in all its bearings to both present and past Home Secretaries, it affords us sincere pleasure now that our efforts have been crowned with success in the release of one whom we believed, and still believe, to be an innocent victim of a hysterical patient and a wrongly directed jury, to commend the testimonial fund to our readers. No amount of money, however large, can of course wipe out the indignity of conviction and imprisonment, but it will at least afford some solace to our *confrères* to know that the profession are satisfied of his innocence, and are determined to express the same in the only practical manner within their power. We commend the letters published in our last week's issue on this subject to the attention of our readers.

#### The Recent Appointment to the Castlebar District Asylum.

ON Monday, the 27th, Mr. Biggar, M.P., put a long series of questions to the Chief Secretary upon the recent appointment to which we referred the week before last in these columns. Mr. Biggar wanted to know how many medical men connected with the English lunatic asylums' service have been promoted during the past ten years to Irish asylums; what number of Irish asylum doctors have been promoted to English asylums? What was the service of the two superintendents prior to their being taken from English asylums and appointed to the Castlebar district asylum, namely, Dr. Conolly Norman, appointed in 1882 or 1883, and Dr. Finigan in 1885; what was the service of the ten principal candidates for the Irish asy-

lum service, namely, Dr. D. Exeter Jordan, of Castlebar; Dr. Taylor, of Dundrum; and Dr. Myles, of the Richmond Asylum, Dublin; what was the official position—and the pay attached to it—held by the medical men in England previously to their appointment by Lord Spencer to the important posts of superintendents of Irish asylums; and whether Earl Spencer directed Dr. D. Exeter Jordan to remain in charge of Castlebar asylum for a period of nearly four months; if so, could he explain for what reason did Earl Spencer appoint as superintendent to the Castlebar asylum another doctor brought from England over the head of Dr. D. Exeter Jordan? To this the Chief Secretary replied that Lord Spencer selected Dr. Finigan, assistant at the Northumberland Asylum. Dr. Finigan is an Irishman and a Roman Catholic, and has very good testimonials. Dr. Jordan, who was consulting physician at Castlebar, was a candidate for that asylum. He acted as *locum tenens* during the vacancy. Dr. Taylor has been assistant at Dundrum for ten years, and Dr. Myles at Richmond for six years. He understood that it is not unusual to appoint outsiders to those posts. Except in the cases of transfer, candidates are generally invited by public advertisement, the object being to secure the best men. This statement is not in the remotest degree a reply to Mr. Biggar's question nor to our complaint. It simply reiterates the fact that Lord Spencer did pass over three experienced and trusted officers of the Department in order to promote a gentleman who, on the Chief Secretary's showing, had no knowledge of Irish lunacy administration, and respecting whom all we know is that he "has very good testimonials." The promotion of Dr. Conolly Norman is entirely a different matter, for he had served long and efficiently in Irish asylums, and had been engaged in England only for a short interval. The fact is admitted that merit, experience, and good service are habitually ignored in the Irish lunacy service in favour of political jobbery, and we shall lose no opportunity of protesting against such motives for dispensing patronage.

#### Paralysis of the Sympathetic.

DR. LEWINSKY reported a case of the above at the last meeting of the Berlin Medical Society. The patient was a woman who had suffered from gastric ulcer, and who as a child had a small goitre which had increased in size during the last ten years. At the time of reporting it was the size of a goose-egg, was seated on the right side, and had curved the trachea to the left. The right upper eyelid drooped, the pupils were diminished in size, the eye lay deeply within the orbit. The fundus oculi was normal. The right side of the face showed almost complete absence of sweat secretion, and the temperature was 0.2° C. lower than on the left. The forearm and hand were occasionally swollen. The temperature of the right hand was 2° C. lower than that of the left. The patient came under observation a second time with hæmatemesis and parotitis. The latter went on to suppuration, and required incision. The secretion of sweat was less and the temperature lower on the right than on the left side. The speaker claimed that the symptoms presented were typical of paralysis of the sympathetic, that the interest of the case consisted in the

long continuance of the cedema without disturbance of the circulation and with normal sensibility and mobility. As regarded the locality of the lesion, the supposition that it was produced by pressure of the goitre would not be far astray.

#### Visit of Her Excellency the Countess of Carnarvon to the City of Dublin Hospital.

THE Countess on Monday, the 27th of July, visited the hospital, attended by her Excellency's suite. She was received by Dr. Hawtrey Benson, physician to the hospital, and by Mr. Wheeler and Mr. Fitzgibbon, surgeons to the hospital, Dr. Banks and Mr. Tufnell, the consulting physician and consulting surgeon, and Dr. Arthur Benson, ophthalmic surgeon. There were also present Mr. Brown, house surgeon, and Miss Beresford, lady superintendent. Her Excellency visited the wards, and evinced much interest in the hospital, and also in the nursing institution which is attached to it, which, it was explained, had been founded only fifteen months since, but had proved to be of the greatest value to the hospital. Her Excellency promised to visit the nursing institution at a future period.

#### Death of Professor Schalger.

PROFESSOR LUDWIG SCHLAGER, Director of the Wiener Landes-Irrenanstalt, Gastein, one of the most distinguished alienists in Austria, died on the 24th ult.

#### The Study of Morbid Anatomy.

THE supreme importance of affording facilities for the study of pathology and morbid anatomy, though theoretically admitted in this country, is not recognised by the authorities in a manner that offers any practical advantages to investigators, and the means for accomplishing the vast amount of work that is notwithstanding done amongst us owes its origin to private enterprise or to the action of private corporations. It is inconceivable what large opportunities are annually lost in London alone of prosecuting studies that would yield an abundant harvest of knowledge in this connection, and solely because of the difficulty that is experienced of convincing the powers that be how much would be gained to science by providing the necessary means of enabling a special pathologist to utilise the materials provided, unfortunately in abundance, for such work by the indigent and criminal classes of the community. In Berlin such opportunities have been provided in the most satisfactory manner in connection with the new Morgue which has recently been completed. A wing of this building is to be devoted to the service of the University Institute of Public Medicine, and to this end provision has been made for a complete suite of post-mortem rooms, laboratories, lecture rooms, and all necessary offices. This institute was originally founded by the famous medico-jurist J. L. Caspar, and the post of Director formerly held by him is now filled by the Town and Forensic physician of Berlin, Professor Loman. Possibly our great towns will by-and-by be no less well provided than Berlin with well-appointed buildings devoted to the study of public medicine, and until this time arrives the importance of such an improvement ought to be constantly insisted upon.

#### The Criminal Law Amendment Bill.

It will give general satisfaction to all classes of the community to learn that the Criminal Law Amendment Bill is assured of passing into law during the present session of Parliament, and on the one important clause contained in it, that, namely, fixing the age up to which the law throws its protection over young girls, the compromise arranged between contending parties is sufficiently reassuring. From thirteen the limit of consenting age is now extended to sixteen, and public opinion will certainly be much more generally satisfied with that decision than if the claims of those who urged eighteen, and even twenty-one, as the age, had been adopted. On many grounds sixteen years possesses advantages in its favour which could not be urged at present in behalf of a higher limit, although it is impossible not to wish that the state of society permitted legislation in behalf of women irrespective of the question of years. We have, however, to keep in view the injury that will be rendered possible under an Act of the nature of that framed to amend the criminal law, and to admit the likelihood that danger to innocent persons will be increased in proportion as the test of years is accepted as the principal basis of judicial proceedings. It is the medical profession which is most open to false accusations in this respect, and its members have only too much cause to be always on their guard against the designs of unprincipled women, as is proved by more than one case of trumped-up charges against practitioners. We accept the change in the law, however, as a salutary one, and for the sake of what good it may possibly do, the profession willingly incurs the extra risk to itself, conscious that the public is always ready to protect its members against those abominable charges which do nevertheless occasionally succeed in bringing temporary disgrace and sore trouble on perfectly innocent men.

#### Prosecution under the Pharmacy Act.

IN the Sheriff Court at Linlithgow, on the 25th ult., John Paris Duguid, watchmaker and jeweller, Bo'ness, was charged at the instance of Mr. Richard Bremridge, 17 Bloomsbury Square, London, registrar of the Pharmaceutical Society of Great Britain, with committing an offence against the 15th section of the Pharmacy Act, 1868, by having on 7th February last, in the premises known as "The Medical Hall," Bo'ness, sold a quantity or kept an open shop for the sale of chloral-hydrate, or a preparation thereof, the same being a poison under the Pharmacy Act, the accused not being a duly registered pharmaceutical chemist and druggist under the said Act. Mr. Strachan, solicitor, Bo'ness, appeared for the accused, and stated the following objections to the complaint:— (1) That the instance was not good, on the ground that the prosecutor was a foreigner, and had not the concurrence of the Procurator-Fiscal; (2) that the complaint did not specify to whom the poison was sold; (3) that the complaint did not set forth the exceptions of the statute, and say that the accused did not come within either of them; (4) that the complaint libelled two alternative offences, either of which could be committed separately, and did not distinguish between selling and keeping an open shop; and (5) that the complaint did

not specify alternatives of punishment. Sheriff-Substitute Melville repelled all the objections, and the accused tendered a plea of not guilty. Evidence was heard at considerable length, and at the close his Lordship held the accused guilty of selling chloral-hydrate, and found him liable in a penalty of £5.

#### The Disadvantages of Prepared Foods.

DR. W. ROBERTS, in his address to the British Medical Association on "Feeding the Sick," made reference to the numerous prepared foods for infants and invalids in which so large a trade is now carried on. He pointed out that these foods, one and all, must necessarily be derived from a limited number of well-known flours, including wheat, barley, oats, maize, pea, lentil, and one or two others. While admitting that these various foods possessed undoubted excellencies, and that they severally are adapted to different cases and conditions, Dr. Roberts, however, insists that it is a great disadvantage that they are all practically secret compounds, and that on this account they are unfitted for the use of the physician. Both the latter and his patient would be more favourably situated if the attendant were able to order a food the exact composition of which was known beforehand, and consequently its effect on the system pregauged, instead of being compelled to trust blindly to a mixture of which he can only approximately guess the contents. In the same way as secret remedies are eschewed by medical men because of the uncertainty attending their composition, so, argues Dr. Roberts with much justice, is there reason for a physician to be chary of ordering his patient a food of which the precise composition is not publicly declared. The question that this opens up, is a very important one, which has not hitherto been sufficiently considered; and it remains to see whether purveyors of the better known foods will not find it most to their own interest to remove the bar of secrecy from their particular preparations.

DRS. TILT, Heywood Smith, Fancourt Barnes, and Bantock, and Mr. Knowsley Thornton have been elected corresponding members of the Gynæcological Society of Boston, U.S.A.

### Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

ABERDEEN, BANFF, AND KINCARDINE BRANCH OF THE BRITISH MEDICAL ASSOCIATION.—At a meeting of this Branch of the British Medical Association, held in the Christian Institute Buildings on Saturday, the 25th ult., Dr. Angus Fraser, in replying to the toast "Success to the Royal Infirmary," which was proposed by Dr. Lyon, animadverted in strong terms on the Managing Committee of the institution. He wished that Aberdeen could boast of a better Infirmary than the present one, which was hardly a credit to the town. The Committee of Management were invested with powers twelve months ago to better the condition of the institution, but they had, he was sorry to say, never put them into practical shape. The Infirmary was in a discreditable state, and it would not be improved until they took

more stringent steps to put it right. The existing state of matters had been repeatedly placed before the Committee plainly and distinctly—indeed they had stated the case so strongly that they had been asked not to exhibit the true condition of things to the public gaze, as it was feared that were the inhabitants of Aberdeen to understand clearly how the matter stood it would create quite a revolution in the public mind, and people would not be satisfied till remedial measures were effected. He was sorry to speak in this manner of the Royal Infirmary, but really if things were not soon attended to they would have to adopt the policy of a certain London journal, and just speak the truth. The Managers, as he said before, had received powers which they had failed to implement. To give an instance of how the management was conducted, the Managers made a rule to the effect that a porter was to be employed at the lodge whose age would not exceed 50 years, and who would be expected to devote a portion of his time to the cultivation of the shrubs and flowers attached to the Infirmary, and they immediately thereafter violated the rule by appointing a man upwards of 70 years of age. That was an example of how things were carried on, and how was it possible, he asked, to improve such Managers?

THE UNIVERSITIES (SCOTLAND) BILL.—A deputation representing the London Committee of the Association of the General Council of the University of Edinburgh had a private interview with Mr. Dalrymple at the House of Commons on the 30th ult. in reference to the Scottish Universities Bill. They presented a petition from the Association, and stated that while generally favourable to the Bill, and desirous to see it passed into law this session, they desired its amendment in certain important particulars. Especially they wished to see an increase in the number of members of the University Council upon the University Court, a strengthening and extension of the powers and functions entrusted to the Court, and the transference to it of the management of all University funds and business at present held by the Senatus. Mr. Dalrymple entered at some length into these various questions, and while the conversation was proceeding he was joined by Dr. Webster, who repeated his statement that he intended to adhere to his opposition to the Bill. Mr. Dalrymple assured the deputation that the views they had expressed would be carefully considered, but he pointed out that there was a more powerful agency working against the Bill than even Parliamentary opposition—and that was time. Any public body, he added, who pressed against a Bill so beneficial in many of its provisions incurred a serious responsibility.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 25th ult., was 62, and the death rate 13 per 1,000. Diseases of the chest accounted for at least 30 deaths, and zymotic causes for 5, of which 1 was due to fever and 1 to measles. The intima-tions for the week comprised—fever 11, diphtheria 1, scarlatina 11, and measles 46.

MORTALITY IN GLASGOW.—The deaths in Glasgow during the week ending with Saturday, the 25th ult., were at the rate of 24 per 1,000 per annum of the population, as compared with 22 in the previous week, and 22, 23, and 25 in the corresponding periods of 1884, 1883, and 1882 respectively.

GLASGOW TOWN COUNCIL.—At a meeting of the Glasgow Town Council, held on the 29th ult., Dr. Russell, the officer of health, reported that during the fortnight ending July 18th, 1885, there were 427 deaths registered, as compared with 454 in the fortnight preceding, a decrease of 27. The

number of deaths of persons aged below 1 year was 119 in place of 96, and of persons aged 60 and upwards, 59 in place of 61. Of the total deaths, 44 in place of 42 per cent were of children below 5 years of age. Of children at school age (viz., 5 to 13 years inclusive) there were 37 deaths registered, as compared with 34, viz.:—1 typhus, 2 enteric fever, 3 scarlet fever, 1 whooping-cough, 1 diphtheria, 7 consumption, 5 acute diseases of the lungs, and 17 from miscellaneous causes. The number of deaths from infectious diseases of children was 33 in place of 51—viz., 24 from whooping-cough, 6 from scarlet fever, and 3 from measles. No cases of small-pox were registered. The number of cases of fever registered was 14 in place of 24—viz., 10 of enteric fever, 3 of typhus, and 1 undefined. There were also registered 67 cases of scarlet fever, 52 of whooping-cough, 42 of measles, and 3 of diphtheria, of which 39 were removed to hospital, and the remainder kept under supervision at home. There were at present in the hospitals, Belvidere, 100 cases of scarlet fever, 41 of enteric fever, 25 of measles, 21 of whooping-cough, 11 of typhus, and 3 of small-pox—in all 201 cases as compared with 195 this day fortnight, and 343 at the corresponding period of last year. During the fortnight 58 cases were admitted to the Fever Hospital, 45 dismissed well, and 6 died. One case (suspected, but found not to be small-pox) has been admitted to the Small-pox Hospital, and 2 dismissed well.

UNIVERSITIES OF EDINBURGH AND ST. ANDREWS.—**MR. ERICHSEN'S CANDIDATURE.**—There has been issued to the members of Council of these Universities a circular, signed by Professor Douglas Maclagan, of Edinburgh, and Professor T. S. Baynes, of St. Andrews, as chairmen of Mr. Erichsen's General Committee. It states that for more than a third of a century Mr. Erichsen has devoted himself to the cause of science, and, as a surgeon, has risen to the front rank of his profession. His treatise on the "Science and Art of Surgery" is a recognised text-book in England and America, and it has been translated into most of the languages of Europe. The circular alludes to his ability and clear powers of exposition, his appointment as Professor of Surgery and Clinical Surgery at University College, London; his knowledge of the working of the system of the Scottish Universities and of their great medical schools; his sixteen years of office as a member of the Council of the Royal College of Surgeons of England, of which he was President in 1880-81; his appointment as a Surgeon-Extraordinary to Her Majesty the Queen, and the honours conferred on him by learned and scientific institutions, home and foreign, including the high honour of LL.D. from the University of Edinburgh, in recognition of his high character and attainments. From these facts (the circular continues) it will be seen that Mr. Erichsen's professional training, life-long experience and familiarity with most academic and educational subjects, render him in all respects singularly well fitted to enter Parliament, and to represent efficiently, not only the great interests of science, learning, and education, but more especially the great medical schools, upon whose future fame and progress the prosperity of the Scottish Universities so much depends. The chairmen have every reason to believe that his sound judgment, great experience, and judicial habit of mind will be of the utmost service to the Universities, and that their highest and best interests will be safe in his hands. A list annexed to the circular contains the names of about 450 graduates resident in Great Britain and Ireland, many of whom are men of great eminence in their several professions. With this circular there has been sent to the medical graduates a letter signed by Sir James

Risdon Bennett, as chairman of the London committee, who remarked that Mr. Erichsen's career, character, and position in the profession are so well known and appreciated that it would be unbecoming to adduce any special proofs of his eminent fitness to represent medical science in Parliament. As upwards of 3,600 members of the General Council of these Universities—more than one-half of the constituency—belong to the medical profession, it is to them that they venture to appeal and to suggest that, on the present occasion, feelings of party politics should be made to give place to the higher considerations of the national advantage to be secured by the return to Parliament, as the representative of these Universities, of one so capable to represent science, especially in its medical aspect, as Mr. Erichsen.

**BRIGADE-SURGEON T. RUDD**, of the Army Medical Staff, who was favourably mentioned in despatches for his services in the Indian Mutiny, has assumed the duties of Principal Medical Officer at Woolwich, vacant by the death of Deputy Inspector General Barnett.

**MR. HENRY FITZGIBBON**, Surgeon to the City of Dublin Hospital, and to the Westmoreland Lock Hospital, has announced his intention of seeking the Vice Presidency of the Royal College of Surgeons in Ireland at the election in June, 1886.

## Correspondence.

### THE CONJOINT EXAMINATION SCHEME FOR IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with surprise the paragraph headed "The Conjoint Examination Scheme for Ireland," which appeared in the *Medical Press and Circular* of July 29th, 1885. You commence that paragraph by stating that the "negotiations for establishing a conjoint examination by the Colleges of Physicians and Surgeons in Ireland has (*sic*) completely broken down;" and, subsequently, referring to the proposed division of the surplus funds, you state that, "On this occasion the College of Physicians has taken higher ground, and has refused to accept any less share than half the money, and has therefore sent back the scheme to be again reported on *sine die*."

This is not an accurate account of what has taken place.

On Wednesday, July 22nd, 1885, the President and Fellows of the King and Queen's College of Physicians held a special meeting to consider the report of a combined committee of the College of Physicians and College of Surgeons, appointed for the purpose of considering and reporting upon an Outline Scheme for a Conjoint Examination, proposed by the Royal College of Surgeons in Ireland for consideration by the King and Queen's College of Physicians.

At this special meeting the report of the combined committee was received, and the College went into committee in accordance with the usual practice. By consent, paragraph 10 of the Report was first taken into consideration. It runs as follows:—

"The surplus from fees, after payment of the expenses of the examinations, shall be divided between the Colleges—the King and Queen's College of Physicians receiving three-eighths and the Royal College of Surgeons five-eighths."

After a prolonged discussion, it was resolved "that paragraph 10 of the Report of the Combined Committee be referred to a Committee consisting of the Censors and the Finance Committee, to report to the College with reference to the financial results likely to ensue." It was further resolved "that the College do adjourn until the report of the Committee on the financial relations of the proposed Conjoint Scheme to this College" (*i.e.*, the College of Physicians).

With the request that you will be good enough to insert this reclamation in the next issue of the *Medical Press and Circular*,

Yours faithfully,  
JOHN WILLIAM MOORE.  
M.D. Univ. Dub., Fellow and Registrar.  
King and Queen's College of Physicians in Ireland,  
Dublin, August 1st, 1885.

[While we acknowledge that Dr. Moore's statement is officially and technically accurate, we are also aware that our representation of the matter is practically and substantially correct. The motion to adopt the Conjoint Scheme was resisted by a majority of the Fellows present, who insisted that nothing less than an equal division of the funds between the two Colleges should be entertained. The advocates of the Conjoint Scheme fought against the proposition to refer back the report for elucidation of the financial point, but they were defeated, and the speakers against the scheme made no secret of their determination to defeat it, no matter what the report of the Committee might be. Their vote was avowedly equivalent to a vote to "read the Bill a second time that day six months." If the Committee reports at all it must report that the College of Physicians stand to lose several hundreds a year by this Conjoint scheme, and thus the already dominant majority against the scheme will be fortified in their opposition to it. We consider ourselves fully justified, under the circumstances, in stating that the negotiations have broken down. Neither the Council of the College of Surgeons nor the College at large would for a moment entertain the proposition for an equal division of the surplus, inasmuch as such a concession would not only humiliate the College, but would increase its loss under the scheme from about £600 a year to £1,000.—ED.]

### Literature.

#### FACE AND FOOT DEFORMITIES. (a)

IN writing a book now-a-days, when so many rush into authorship, it may be asked the object of the present volume, considering the amount of literature we have already on the same subjects. And without altogether attempting to dissuade surgeons with reasonable ambition from rushing into print, we think, however, that when it is decided to write a book, the author should first consider whether he can throw any new light on a given subject, or whether what he writes will be worth reading. After a careful perusal of 195 pages we have come to the conclusion that we find nothing very new in this volume. The title of the work, to say the least of it, is somewhat indefinite, but the author attempts to justify the selection when he says—"It may be asked why I should associate the face with the foot, as these are the two extreme parts of the body? Chiefly because deformities of these members of the body being more manifest than deformities elsewhere, they constitute a greater hindrance to success in life. They not only deform, but deface, by reason of their great disfigurement, the artistic proportions of those parts of the body upon which the eye of the observer or critic most loves to rest." The author has included so many subjects under the two groups that he has been forced to be so brief and superficial concerning many of the subjects mentioned that the information thus given fails to be instructive or interesting.

We may appear to have been unnecessarily severe in our notice of the author's labours—for we are aware of the labour of bringing out such a volume—but we venture to hope that future editions may rectify many of the defects the present issue contains.

The book is illustrated with some very well executed original chromos and monotonos. Some of the woodcuts are quite familiar with, but they are nevertheless well selected.

(a) "Face and Foot Deformities." By Frederick Churchill, C.M., Surgeon to the Victoria Hospital for Children. With illustrations of New Appliances for the Cure of Birth Marks, Club-Foot, &c. London: J. & A. Churchill. 1885.

#### CLINICAL NOTES ON CANCER: ITS ETIOLOGY AND TREATMENT. (a)

THIS little work of ninety-three pages seeks to convey as briefly as possible the author's practical experience of several years' work among cancerous patients. No attempt has been made at elaborate descriptions or exhaustive investigation, but the impressions received through constant familiarity with everyday cases, and the deductions to which they give rise in the author's opinion are set down "without prejudice." In the chapter on the cause of cancer the author endeavours to prove the error in believing that heredity has anything to do with the production of the disease, but rather inclines to the belief in the neurotic origin of most cases of alveolar cancer. We are inclined, however, not to agree with the author in this theory. All subjects in connection with the disease are plainly and practically stated, and although one may differ here and there with the author's views, the book will prove useful to those interested in the study of this dread malady.

#### ST. THOMAS'S HOSPITAL REPORTS. (b)

THE present volume has been brought out with the same care as last year, containing some valuable and practical papers. The first paper, on "Some Records of Surgical Experience," from the pen of Mr. F. Le Gros Clark, F.R.S., is well written, and alludes to a variety of important subjects met with in surgical practice. Many other contributions on medicine, and surgery, with special reports from the skin, obstetrical and ophthalmic departments for the year 1883 are also found in these Reports, and will well repay a careful perusal.

### Medical News.

Royal College of Physicians of London.—The following candidates, having passed the necessary examinations, were admitted Members on Thursday last, July 30th:—

Anderson, John, M.D. St. Andrews, 105 Gloster Place, W.  
Fox, Richard Hingston, M.D. Brussels, 43 Finsbury Circus, E.C.  
Halliburton, William Dobinson, M.D. Lond., 135 Gower Street, W.C.  
Shadwell, Arthur, M.B. Ox., Brighton.  
Thomson, St. Clair, M.B. Lond., 18 Gloster Walk, W.  
Woodriddle, Leonard Charles, M.B. Lond., Guy's Hospital, S.E. 1

The following were admitted Licentiates on July 30th:—

<p>Allan, James Hugh Brodie Angior, Thomas Matthews Austin, Herbert Ward Barker, William J. Townsend Bent, George Broekat, Andrew Alexander Chapple, Aubrey Durant Chittenden, Thomas Hillier Clarkson, Frank Cecil Clendinnen, Frederick John Curgenven, John Sadler Dagg, Trevor Augustus Dearden, William Francis Dodd, Walter Henry Du Bulson, Edward William Evans, John Morgan Foulerton, Alex. G. Russell Gough, John Harley Gow, Duncan, M.D. Toronto Habgood, William Hore, Harry George Standish Hunton, Alfred William Jaboor, Habeeb Jaboor, Hanna Jacobson, Thomas Brander Jarvis, John</p>	<p>Jervis, Arthur Lloyd, Percival Allen Lynch, George W. Augustus Moore, Walter Henry Bernard Oliver, John O'Reilly, Archibald Thomas Parsons, Harry Compton Pring, Frederick Arthur Pritchard, Joseph J. Gasler Rayne, Herbert Edward Rushbrooke, Thomas Schofield, Gerald Shadwell, Harry Winstanley Smith, George Francis Smith, John Steinthal, Walter Oliver Sykes, Thomas Hindle Wagstaff, John Philip Walker, Henry Secker Walton, John White, Frank Faulder Whiteley, Daniel Flockton Williams, Campbell Williams, Edward Lloyd Wilson, Albert Woutersz, George Justin.</p>
--	---

Aberdeen University.—On the 31st ult. the following received the degrees of M.D., and M.B., and C.M.:—

*The Degrees of M.D.*  
William Barron, M.B., C.M.; Clarence William Haig Brown, M.B., C.M.; Alexander Campbell, M.B., C.M.; Robert John Gollie, M.B., C.M.; William Cooper, M.B., C.M.; Herbert William Tolver Crow, M.B., C.M.; Francis Carteret Gayton, M.B., C.M.; Alfred Hodgson, M.B., C.M.; Andrew Hostie, M.B., C.M.; James Leith Leslie, M.B., C.M.; Alexander Macgregor, M.B., C.M.; Alexander MacLean, M.B., C.M.; Deputy Surgeon-General; Thomas Marsden, M.B., C.M.; William Adam Michte, M.B., C.M.; James Thomas Mitchell, M.B.,

(a) "Clinical Notes on Cancer: Its Etiology and Treatment." By Herbert L. Snow, M.D. (Lond.), Surgeon to the Cancer Hospital, Brompton. London: J. & A. Churchill.

(b) "St. Thomas's Hospital Reports." New Series. Edited by Dr. Seymour J. Sharkey, and Mr. Francis Mason. Vol. XIII. London: J. & A. Churchill. 1884.

C.M.; Charles Louis Isidore de Sellan, M.B., C.M.; William Simpson, M.B., C.M.; William Henry Stewart, M.B., C.M.; William Stuart, M.B., C.M.; George Vincent, M.B., C.M.

*The Degrees of M.B. and C.M.*

Alfred William Alcock, Charles Spencer Anderson, John Anderson, M.A.; Matthew Ferguson Anderson, William Robert Cheves, John Christie, M.A.; David Macdonald Brown, Charles Alexander Butchart, Alexander Gray Connan, Andrew Hunter Cowan, John Stuart Davidson, Edward Greaves Wooding Deane, John Duncan, M.A.; John Francis Scott Fowler, Frederick Arthur Foy, David M. Gill, Henry William Godfrey, James William Mackenzie Gunn, M.A.; Herbert John Hargrave, Albert Edward Henderson, George Nicol Henry, John Watson Hutcheon, John Charles Davidson Irvine, James Eddington Jeffris, Francis Grice Jones, John Marshall Lamb, M.A.; John Mackenzie, John Marsden, Alexander Milne, James Black Milne, James Shaw Milne, William Vincent Morgan, Thomas George Paterson, Arthur Edward Paterson, Patrick Whyte Rattray, M.A.; George Scott, David Simpson, M.A.; William Bulmer Simpson, John Rutherford Skinner, Arthur Greatorex Smith, William Gordon Stott, M.A.; Alex. James Stuart, Peter Alfred Sullivan, David Taylor, Andrew Whyte.

Of the above-named candidates, John Marshall Lamb, M.A., Alexander Milne, Patrick Whyte Rattray, M.A., Arthur Greatorex Smith received their degrees in medicine and surgery with highest academical honours; Alfred William Alcock, John Stuart Davidson, Henry William Godfrey, George Nicol Henry, Francis Grice Jones, James Black Milne, Thomas George Paterson received their degrees in medicine and surgery with honourable distinction. The John Murray medal and scholarship was awarded to Patrick Whyte Rattray, M.A., as the most distinguished graduate of this year. At the same time, Charles Mitchell Aird, Leslie Durno, John Malcolm, James Murray, Cecil Robertson, John Hutton Stenhouse were certified as having passed all the examinations, but did not graduate.

**Royal Colleges of Physicians of London.**—At the meeting of the College on Thursday last the following officers were elected:—Censors: Drs. Habershon, W. H. Stone, J. E. Pollock, and W. H. Dickinson. Treasurer: Dr. Dyce Duckworth. Registrar: Sir Henry Pitman. Harveian Librarian: Dr. W. Munk. Assistant Registrar: Dr. Alchin. Curators of the Museum: Drs. Weggs, Lionel Beale, Bastian, and Curnow. Finance Committee: Drs. Hare, William Wood, and Edward Liveing. Examiners in Chemistry and Chemical Physics: Mr. C. W. Heaton, Dr. Thomas Stevenson, Dr. Bernays, Dr. W. J. Russell, and Mr. William Foster. Examiners in Materia Medica, Medical Botany, and Pharmacy: Drs. Brunton, Mitchell, Bruce, Frederick Taylor, William Murrell, and D. B. Lees. Examiners in Elementary Physiology: Drs. William Ewart, and V. D. Harris. Examiners in Physiology: Drs. John Harley, Leonard Woodriddle and Schäfer. Examiners in Osteology and Anatomy: Drs. Carrington and Jas. Anderson, and Mr. Henry Morris. Examiners in Medical Anatomy and Principles and Practice of Medicine: Drs. Lionel Beale, Sturges, Sutton, Church, Cheadle, Pye-Smith, Green, Bastian, Cayley, and Whigham. Examiners in Midwifery and Diseases peculiar to Women: Drs. Jervis, John Williams, and James Watt Black. Examiners in Surgical Anatomy and Principles and Practice of Surgery: Messrs. George Pollock, John Couper, and Marcus Beck.—At the same meeting the following was presented:—"The Committee have to report that they have fully considered the question referred to them, viz., the advisability and practicability of granting the title of Doctor to persons who have obtained the diplomas of the two Colleges. They have also considered the memorial, signed by more than 600 teachers, practitioners, and students in medicine, and referred to them, advocating the amalgamation of the two Colleges into one Royal College of Medicine, for the purpose of granting degrees in Medicine and Surgery. After careful deliberation the Committee have unanimously agreed to the following resolutions as expressive of their opinion on the subject: 1. That it is desirable that persons examined by the Royal College of Physicians of London and the Royal College of Surgeons of England conjointly, and found duly qualified, should, in virtue of that examination, have a degree in Medicine and Surgery conferred upon them. 2. That the curriculum of study and the examinations to be undergone for the licence of the Royal College of Physicians of London and the diploma of the Royal College of Surgeons of England are equal to those required by most of the universities for degrees in Medicine and Surgery. In conclusion, the Committee are of opinion that, should the two Colleges approve the foregoing resolutions, means could be found for giving effect to them."

**Royal College of Surgeons of England.**—The following

candidates, having passed the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on July 23rd:—

Acock Harry, L.K.Q.C.P.I.  
Angior, Thomas Matthews, L.S.A.  
Brentnall, Frederick, L.K.Q.C.P.I.  
Bowman, Reginald, M.B. Edin.  
Bowman, Henry Claxton, L.S.A.  
Clarke, John Michell, M.B. Cantab.  
Collinson, Frederick W., M.B. Ed.  
Crowther, John Woodward, L.S.A.  
Gibson, John Lockhart, M.B. Ed.  
Hughes, Alfred William, M.B. Ed.  
Lamont, John Charles, M.B. Ed.

Lees, Edwin Leonard, M.B. Ed.  
Lightford, Charles Louis, M.B. Ed.  
Parker, George, M.B. Cantab.  
Porter, William Ernest, M.B. d  
Proud, Frederick, M.B. Durh.  
Beece, Richard James, L.S.A.  
Robertson, Ernest, M.B. Ed.  
Shackleton, Herbert, L.K.Q.C.P.I.  
Thomson, Henry Alexis, M.B. Ed.  
Warnock, John, M.B. Ed.

The following were admitted on July 24th:—

Achard, Alexander Louis, L.S.A.  
Bronner, A., M.D. Heidelberg  
Buss, Howard Decimus, L.S.A.  
Clarke, J. St. Leger, L.K.Q.C.P.I.  
Cones, John Archibald, L.S.A.

Fitch, Charles Dennis, L.S.A.  
McLachlan, John, M.B. Ed.  
Stephen, William H. G., M.B. Ed.  
Sykes, T. Hindle, L.R.C.P. Lond.  
Thompson, Stephen Robert.

The following were admitted on July 27th:—

Bigger, W. Grimshaw, L.S.A.  
Brockett, Andrew A., L.E.C.P. Lond.  
Buxton, Edward, L.E.C.P. Ed.  
Jarvis, John, L.E.C.P. Lond.  
Kauffmann, Otto Jackson, L.S.A.

Oliver, John, L.R.C.P. Lond.  
Eushbrooke, Thomas, L.S.A.  
Schofield, Gerald, L.R.C.P. Lond.  
Smith, Samuel Gordon, S.A.  
Whiteley, D. F., L.E.C.P. Lond.  
White, John Hall, L.R.C.P. E.

The following were admitted on July 28th:—

Blakemore, Benjamin, L.K.Q.C.P.  
Brown, Lewis, L.S.A.  
Dobson, Leonard C. Talbot, L.S.A.  
Grant, James E. R., L.K.Q.C.P.  
Lees, William, L.S.A.

Luckham, Levi Stephenson, L.S.A.  
Moore, William G., L.R.C.P. Ed.  
Saville, Henry W. Brooks  
Wingrave, Thomas, L.S.A.  
Winship, William A., L.S.A.

The following were admitted on July 29th:—

Burton, Frederick W., L.E.C.P. Lond.  
Clarkson, Frank C., L.E.C.P. Lond.  
Du Buisson, Ed. Wm., L.E.C.P. Lond.  
Gell, Henry Willingham  
Hickey, Evan Lewis, L.S.A.

Hore, H. St. Geo., L.R.C.P. Lond.  
Jones, Thomas Slater  
Moore, Walter H. B., L.R.C.P. Lond.  
Saw, Francis Albert, M.B. Durh.  
Smith, John, M.R. Edin.  
Taylor, Charles Henry, L.S.A.

**Royal College of Surgeons in Ireland.**—The following candidates have passed the July examinations for the Licence of this College:—

*Second Examination.*

Abbott, John  
Beamish, Benjamin  
Bewley, Alfred W.  
Boyce, Chas. E.  
Brabazon, Edw. O.  
Byrnes, John J.  
Casey, Joseph W.  
Cowen, Thos. E.  
Cox, Stafford M.  
Cremin, Wm.  
Grumley, James  
Delany, Rowland  
Fraser, Edward  
Frizell, Wm. A.  
Glynn, Eugene  
Gore, Wm. E.  
Graves, Wm. E.  
Hamilton, John G.  
Greene, John F.  
Hayes, Henry B.  
Hewitt, Richard J.  
Hughes, Chas. J.  
Hust, Richard E.  
Johnston, George A.

Ludlow, Victor E.  
Lyons, Chas. J.  
Magner, Daniel  
Mulqueen, John  
Mardin, James  
M'Dermott, Henry  
Meek, John E.  
M'Naboe, John J.  
Murphy, Denis P.  
O'Connor, James  
Hill, Francis  
Pentony, Eugene P.  
Shanley, Michael  
Shehan, Thomas A.  
Skelly, Laurence  
Sparling, John E.  
Sprowle, Arthur B.  
Stewart, John.  
Swan, James H.  
Taylor, Wm. K.  
Teahan, Timothy  
Trant, James  
Wynne, Wm. P.

Twenty-five were referred.

*Third Professional Examination.*

Barton, Thos.  
Roiger, Patrick  
Cluterbuck, Austin B.  
Connellan, Thos.  
Corcoran, Edward  
Dick, Wm. B.  
Geary, Michael J.  
Goodman, Thos. G.  
Hopkins, Bartley H.  
Hugo, Richard N.  
Jacob, Edmund J.  
Langan, John  
Long, Sinclair  
Mathews, Henry J.  
M'Dermott, Philip

Nally, Jeremiah E.  
O'Brien, John W.  
O'Donohoe, Francis G.  
O'Loghlin, Denis J.  
Pennafather, Richard  
Power, Everard M.  
Reid, Francis J. D.  
Roas, Wm. L.  
Scott, Wm. J.  
Strangman, Thos. H.  
Wilson, Thomas H.  
Woodwright, Charles  
Woodwright, Wm. H. E.  
Yeates, Edward.

Twenty-one were referred.

**Phosphoric Acid.**—This acid is now extensively and successfully used as a substitute for citric and tartaric acids in mineral waters, not only on account of its relative cheapness, but also because of its freedom from lead and other objectionable impurities. Phosphoric acid and the acid phosphates of ammonia, potash, and lime are also offered as substitutes for tartaric acid and cream of tartar in baking powders.

## Notices to Correspondents.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**READING CASES.**—Cloth board cases, gilt-lettered, containing 26 strips for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

**LOCAL REPORTS AND NEWS.**—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

**DR. BURTON.**—We think it would be wiser not to give insertion to the article unless it is particularly desired, and then a few alterations would of necessity have to be made in it. The strictures are, however, more than deserved.

**DR. MACPHERSON.**—A gentle laxative will be found much more serviceable in such cases than the purging medicines you mention. The daily use of an enema of warm water persevered in for a few mornings ought first of all to be tried.

**MR. DIBBINS.**—There is not any sufficient reason why the course you have adopted should be persevered in. If your opponent persists in such unprofessional practices, it will better become you to show your own appreciation of the rules which influence practitioners in their relations towards each other.

**DR. CORNISH.**—Many thanks for your offer, which, however, we cannot just now avail ourselves of, owing to unusual pressure on our space.

**W. G. G.**—Not unless you can produce receipts for the payments in each case.

**MR. MANLEY.**—You are in error in thinking that the prescription was incorrectly copied. We have carefully compared it with the original, and they agree in every particular. Have you assured yourself that the dispenser was not to blame in the matter?

**MR. THOMAS (Burnley).**—You will find an admirable address on the subject in Sir James Paget's "Lectures and Essays" on cases that bone-setters cure; and Mr. Howard Marsh also has written some valuable articles in connection with the same subject.

**DR. PARKINSON.**—The formula is an old one, and is superseded by more than one of the antipyretic remedies recently introduced to the notice of the profession.

**MR. WINDER.**—The "Liquor Cinchona (Pauli)," introduced by Messrs. Savory & Moore, is a most admirable preparation, and we cannot recommend anything more likely to fulfil the requirements you have laid down.

### THE CASE OF DR. BRADLEY.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—As the recent conviction and imprisonment of Dr. Bradley has practically ruined him, it has been kindly suggested by a number of members of the profession and others, including Sir Wm. Jenner and Mr. Marston C. Buzzard, Q.C., M.P., that a fund be raised for the purpose of helping him to recommence practice. Would you kindly allow an appeal to be made on his behalf through the columns of your journal? Dr. Bradley has a delicate wife and one child, who are now entirely dependent upon the charity of friends and relations. I shall be happy to receive subscriptions, and will give any explanation required.

I remain, yours faithfully,

RICHARD JEFFREYS, M.R.C.S.

Eastwood House, Chesterfield,  
July 28th.

[Our correspondent's letter was evidently penned before he had seen a similar proposal advocated by us editorially and in a letter by Dr. Martin, of Sheffield, in our last week's issue. It, however, affords us gratification to receive this additional and disinterested proof of goodwill towards Dr. Bradley, and to express a hope for an unbounded success to the fund.—Ed.]

**MR. HIBBERT (Liverpool).**—We have not seen the results referred to, but from the most recent experiments of Loesen it has been proved that there exists a close relationship between the alkaloids tropine, cocaine, eugonine, and isotropine.

**L.R.C.P. (Edinburgh).**—It may now be considered as impossible for the Bill to pass during the present session.

**FATHERFAMILIAS** will find all the information he seeks on reference to our Students' number, published Sept. 2nd, 1884.

### OPERATION DAYS AT THE LONDON HOSPITALS.

**MONDAY**—Hospital for Women, 3 p.m.—Metropolitan Free, 3 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Orthopedic, 3 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Mark's, 2 p.m.  
**TUESDAY**—Cancer Hospital, Brompton, 3 p.m.—Guy's, 1.30 p.m.—St. Mark's, 9 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Westminster, 3 p.m.—West London, 3 p.m.  
**WEDNESDAY**—Great Northern, 3 p.m.—London, 2 p.m.—Middlesex

1 p.m.—National Orthopedic, 10 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Samaritan Free Hospital for Women and Children, 2.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Mary's, 1.30 p.m.—St. Peter's, 3 p.m.—St. Thomas's, 1.30 p.m.—University College, 2 p.m.

**THURSDAY**—Central London Ophthalmic, 1 p.m.—Charing Cross, 2 p.m.—Hospital for Diseases of the Throat, 3 p.m.—Hospital for Women, 2 p.m.—London, 2 p.m.—North-west London, 2.30 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. George's, 1 p.m.

**FRIDAY**—Central London Ophthalmic, 3 p.m.—East London Hospital for Children, 2 p.m.—Guy's, 1.30 p.m.—King's College, 3 p.m.—Royal London Ophthalmic, 11 a.m.—Royal South London Ophthalmic, 3 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Thomas's (Ophthalmic Department), 2 p.m.

**SATURDAY**—King's College, 1 p.m.—London, 2 p.m.—Royal Free 9 a.m. and 3 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 1.30 p.m.

## Vacancies.

Clonmel District Lunatic Asylum.—Assistant to Resident Medical Superintendent. Salary, £150, with apartments, &c. Election August 10. (See advt.)

Croydon General Hospital.—House Surgeon. Salary, £100 per annum, with board, &c. Applications, with testimonials, to the Hon. Sec., not later than August 7.

Lincoln County Hospital.—House Surgeon. Salary, £100 per annum, with board, lodging, &c. Applications, with testimonials, to the Secretary, on or before August 15.

Mason Science College, Birmingham.—Demonstrator in Physiological Department. Applications on or before August 20.

Royal Berkshire Hospital, Reading.—House Surgeon. Salary, £90 per annum, with board and lodging. Applications, with testimonials, to the Secretary, by August 15.

Stockton-upon-Tees Hospital and Dispensary.—House Surgeon. Salary, £200 per annum. Applications, with testimonials, to the Secretary, not later than August 24.

Truro Union.—Medical Officer and Public Vaccinator for the District of St. Just. Salary, £20 per annum. Applications, with testimonials, to the Clerk, on or before August 11.

## Appointments.

DYSON, W., B.A., M.D. Lond., Physician to the Sheffield General Infirmary, and Joint Lecturer in Medicine at the Sheffield School of Medicine.

HEYCOCK, F. R., M.D., M.C., F.R.C.S. Ed., Honorary Surgeon to St. Peter's Hospital for Stone, London.

JONES, J. H., M.B., M.R.C.S., House Surgeon to the Clinical Hospital for Women and Children, Manchester.

LITTLETON, F. R., M.R.C.S., Medical Officer for the Aahbourne District of the Aahbourne Union.

MYERS, C. J., M.R.C.S., L.S.A. Lond., Medical Officer for the South District and Workhouse of the Louth Union.

WASSER, G. M., M.R.C.S., L.S.A. Lond., Medical Officer for the Third District of the Okehampton Union.

WOODROFFE, A. W., M.B. Dub., L.R.C.S. I., Medical Officer for the South-Western District of the Billesden Union.

## Births.

CARLETON.—July 26, at Delvin, Co. Westmeath, the wife of William Carleton, B.A., M.B. Dub., L.R.C.S.I., L.M., &c., of a son.

MORTON.—July 27, at Wallasey Villa, Croydon, the wife of Shadforth Morton, M.D., M.R.C.S., of a son.

O'FLAHERTY.—July 28, at Kingstown, the wife of Richard G. O'Flaherty, M.D., of a daughter.

## Marriages.

BROWNE—HITCHINS.—June 25, at Octacamund, India, Surgeon-Major W. R. Browne, M.D., Indian Medical Service, to Edith, eldest daughter of Colonel Hitchins, late Bengal Royal Artillery.

LONG—BIANCHI.—July 30, at Christchurch, Blackfriars, Surgeon J. W. F. Long, Army Medical Staff, to Alice, daughter of Robert Bianchi, M.R.C.S.

## Deaths.

BARNETT.—July 24, at Eastbourne, Sussex, from illness contracted on field service at Suakin, Deputy Surgeon-General Oliver Barnett, C.I.E., Army Medical Department.

CHAPMAN.—July 23, at Kirbymooraid, Richard Chapman, M.D., F.R.C.S. (M.R.C.S. in 1819), aged 88.

CROZIER.—July 26, at Twickenham, George Crozier, M.R.C.S., late of Hindon, Wilts.

ELLIS.—July 22, at Westward Ho, North Devon, after a long illness, Robert Ellis, M.R.C.S., L.S.A. Lond., late of 63 Sloane St., London, aged 62.

GILLITTLE.—July 25, at Whitehall, Pontesbury, from a fall from his horse, Alfred Allen Gillittle, M.R.C.S., aged 96.

SHEPHERD.—July 26, at Brunt How, Amblede, Augustus Burke Shepherd, M.D. Oxon., Physician to St. Mary's Hospital, London, aged 46.

TIMMINS.—July 23, at Priory Street, Carmarthen, John Aaron J. Timmins, M.D., aged 42.

WITCHELL.—July 26, at The Acre, Stroud, Edwin Aubrey Witchell, M.B., C.M. Edin., aged 24.

### THE EMERGENCIES OF SURGERY.

Being a Course of Lectures Delivered in the MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

By LAMBERT HEPENSTAL ORMSBY, M.D., F.R.C.S.,

Lecturer on Clinical and Operative Surgery, Surgeon to the Meath Hospital and County Dublin Infirmary; Surgeon to the Children's Hospital, &c.

#### LECTURE I.

##### INJURIES OF HEAD AND FACE.

INJURIES of the head are at times followed by the most alarming symptoms, even when the appearance and size of the injury are of the most apparently trivial character. The patient after a fall or blow may seem to recover the shock, and to suffer no bad effects. However, in the course of a few hours the patient may become comatose. Mr. Guthrie mentions on this subject "Injuries of the head affecting the brain are difficult of diagnosis, doubtful in their character, treacherous in their course, and for the most part fatal in their results." It must, however, be borne in mind that the truth of this observation does not always follow, for in some exceptional cases, no matter how severe the injury may appear, the patient may recover without a bad symptom, and in the whole course of surgical practice no case presents itself to the surgeon ready for any emergency so important as these forms of injury. No hasty diagnosis should be formed, no heroic line of treatment adopted more than an anxious careful attention to each symptom as it arises. Mr. Liston has also stated with reference to this subject "that wounds of the head of the most trivial character are not to be despised, or of the most severe not to be despaired of."

Contusion of the scalp may result from falls or blows from blunt instruments, the immediate effect of such an injury is great swelling, tension and pain; the integument

over the spot becomes glazed and tender, in a few hours it may become discoloured by extravasation of blood into the subcutaneous tissue. Children are very liable to such injuries by falling off chairs or tripping when at play and their head coming in contact with some hard substance. Anxious mothers and nurses are in the habit of applying a variety of nursery remedies for such to keep down the swelling and prevent the skin turning black.

*Treatment.*—Immediately after the injury the local application of a small piece of ice, or the application of a flat piece of steel or iron, or a flat stone. Almond oil or camphorated oil is also a favourite remedy to apply to the part at once. The application of vinegar and water or a spirit lotion on lint is also most useful. Where the skin is not broken, clearing out the bowels with a mild saline purge. A non-stimulating diet and perfect quietness would be about all that need be done in slight cases. In severe contusions where a large blood tumour immediately forms, the diagnosis and treatment may be more perplexing, for it must be remembered that this has frequently been mistaken for a depressed fracture of the skull, and *vice versa*. In general terms the diagnosis can be made out pretty well by the history of the case. In a bloody tumour of the scalp if it is carefully examined with the finger it is found that there is a circumscribed tumour present with a well defined firm margin, and in the centre of which the finger, as it were, sinks into a soft depressed centre. In a fracture with depression the circular margin is not at all so apparent, and the depression is hard instead of soft to the touch, and if the depression has existed for any time it is most probable symptoms of compression will be present.

Treatment for severe contusions consists in the application of cold evaporating lotion to cause the extravasated blood to be absorbed. In other cases suppuration may take place in the tumour, and when this is evident an incision must be made, and a free exit given to the matter. Erysipelas and diffuse abscess of the scalp may occasionally follow such injuries, whether trivial or

severe, together with inflammation of the brain and its membranes.

*Pott's Puffy Tumour* indicates the presence of a collection of pus situated between the dura mater and the cranium, with a puffy and swollen condition of the epicranial aponeurosis following a severe blow or contusion. When this condition is present probably slight symptoms of compression will begin to make their appearance.—*Treatment*.—Keep the patient in bed in a dark room on light and non-stimulating diet. When evidence of compression appears the operation of trephining over the seat of the injury to give exit to the matter should be performed without delay.

*Wounds of the Scalp* are of common occurrence whether the result of falls or blows with blunt or sharp cutting weapons. As a rule these wounds bleed very profusely, in some instances the smaller branches of the temporal and occipital arteries are severed and require to be commanded either by pressure, ligature, forson, or acupressure needle. A portion of the scalp may be considerably torn and partially detached, as after mill accidents or railway smashes.

*Treatment*.—In a clean-cut incised wound, remove all dirt or foreign matter that may have found its way into the wound. Cut the hair very close about the edge of the wound, and evenly approximate its edges with good adhesive plaster. Do not apply sutures in an old maxim you are expected to follow. Some part of the scalp may slough, however. This will be repaired by healthy granulating tissue. Abscesses may form, which must be evacuated as soon as recognised. All hæmorrhage stopped by pressure or other means; edges of wound brought evenly together; the patient kept quiet; the bowels kept moderately open by saline purges, and light, non-stimulating diet ordered for the first few days—comprises nearly all that need be done in a case of the kind.

*Erysipelas of the Scalp*.—A complication that occasionally arises after a contusion, a punctured or incised wound of scalp. Much depends on the state and constitution of the patient at the time of the accident, as well as the sanitary and hygienic conditions, which may be at fault. The premonitory symptoms of erysipelas coming on are as follows:—Locally, wound becomes glazed and dry, no pus appears on edges; a deep red blush over the part is very apparent, also tingling, heat, and swelling, giving rise to much pain. Constitutionally we have a high temperature, a dry, furred tongue, a quick pulse, loss of appetite, high-coloured and scanty urine, headache.

*Treatment*.—A linseed poultice should be applied if the swelling is very great with a swollen and puffy condition of the epicranial aponeurosis. Incisions should be made with caution, to relieve tension, and warm fomentations. The bowels should be kept clear, and iron, quinine, opium, and strong beef-tea administered internally.

*Fractures of the Skull*.—Of this we have many varieties. Generally, however, it is divided into fracture of the vertex and fracture of the base. Of the vault, or vertex, we have *depressed*, a small portion of bone is driven inwards, and *non-depressed*, where there is no separation or depression, but just simple linear fissure of the cranial bones in one or more directions. The outer table may be furrowed or grazed by the passage of a ball across the skull. Much of the scalp must be necessarily torn and separated from the bone, which will in all probability produce necrosis, sloughing, abscess, ulceration, and sympathetic inflammation of brain and membranes.

*Treatment*.—The same as adopted in other head injuries. Wound treated on general principles. Contusion of the scalp with depressed fracture without a wound. This kind of injury may puzzle one what to do. But the general rule in surgery is to adopt the following course: Where you have no wound, no symptom of compression, but with depression wait for symptoms to arise before attempting to trephine or elevate, as before doing anything, you must necessarily convert a simple fracture into a compound. 2. Where you have a wound in the scalp communicating with the seat of depressed fracture

elevate or trephine, whether you have symptoms of compression or not. Sir Wm. McCormac mentions on this subject what I may be allowed to quote with advantage: "One point regarding which opinions vary somewhat is respecting the treatment of depressed fracture unaccompanied by symptoms and with an external wound. Where there is no wound he would be a hardy operator who should cut down upon a depression in the skull in the absence of any symptom of compression. When there is a wound, however, the case is different; but even here I question much if the surgeon ought to do more than simply remove such loose fragments as can readily be got at."

Fracture of one table singly without the other is sometimes spoken of as regards the inner table, but its frequency is a matter of considerable doubt, and Guthrie mentions he has never seen it occur without positive marks of injury on the bone or pericranium.

*Treatment for fractures of all parts of the vertex, it must be remembered, that as regards the result, recovery is far more likely to occur than those of the base. If it is merely a linear fracture the patient should be kept quiet, cold water dressing applied. Sometimes profuse suppuration follows, when it is advisable to apply a light linseed-meal poultice. If a portion of bone has been driven in on the brain, together with the missile or bullet that produced the fracture, an attempt should be made to remove it. The fragments sometimes get displaced for some little distance under the cranium, away from the opening, in which case the removal is difficult, and any undue manipulation or exploring may drive the foreign body farther in on the brain, to be followed by greater injury and fatal cerebral mischief. By gentle manipulation with a probe, elevator, and forceps it is sometimes easy to remove the fragments. And in all cases elevation should be adopted and practised in preference to trephining where feasible, as the operation is much more simple and much less dangerous to the patient. The operation of elevation is thus performed:—If the wound is not large enough it may be increased by incision with a scalpel. The epicranial aponeurosis should be gently raised with a forceps, so as to see clearly the amount of depression and the line of fracture. A probe may then be passed between the fissure so as to ascertain whether the depressed portion is movable or not. If it is, the elevator is then gently insinuated in the fissure and the finger placed flat at edge of wound acts as a fulcrum for the elevator or lever to work on. If a sharp point of a spicula prevents the elevator being used this portion may be sawn through with a Hey's saw. After removal all hæmorrhage must be arrested, which generally wells up out of the wound, cold water dressing applied, and the patient carefully watched. Suppose this operation of elevation cannot be adopted, he must then have recourse to the more severe form of procedure, viz.:—*

*The operation of Trephining*.—Before commencing such an operation the surgeon will provide himself with the following:—1. A razor, to shave the hair; 2. Scalpels; 3. Two medium sized trephines; 4. Hey's saw; 5. Elevator; 6. Brush to clear the wound and trephine of bone dust; 7. Probe; 8. Dissecting or dressing forceps; 9. Quill or toothpick to explore the groove made by trephine; ligatures, lint, ice, bandages, artery forceps, and tenaculum, sponges, &c., ether inhaler.

If the spot of the skull can be selected it is well to remember there are certain parts of the cranium it is recommended not to apply the trephine, viz., over sutures, over venous sinuses, near anterior angle of parietal bone, over middle meningeal artery, near base of skull. In many cases, however, the surgeon is compelled to apply the trephine where he finds the seat of depressed fracture, but he can still bear in mind that the trephine can be applied even if a wound is made for him in a direction as far removed as possible from any structure which should be necessarily avoided.

The operation is thus performed: Place the patient in the recumbent position, in a situation where the surgeon

will have good light. If the patient is unconscious an anæsthetic need not be given. Shave the hair some distance round the wound or the situation where you intend to operate. If a wound is already present enlarge it in whatever direction it will give sufficient room. If you find in making this incision you cut a small vessel arrest it at once either by torsion, ligature, or acupressure needle, as the blood welling out of the wound will only destroy your vision of the parts beneath and distract you. If no wound is present you must either make a V or a T or a + incision in the scalp, then gently raise the epicranial membrane, having bared the bone clearly all round, so as to ascertain exactly the extent of the depression, then apply the trephine, placing *two-thirds* on the crown of the sound or non-depressed bone, and *one-third* on the depressed; by so doing, you will avoid the danger of displacing or depressing the splintered bone down on the membrane of the brain. The trephine at first must be firmly pressed down into the skull so as to allow the centre pin to penetrate into the outer table, the trephine is then gently rotated in half turns by a to-and-fro motion. When the cutting edge of the instrument has fairly cut through the out-table the centre pin must be withdrawn and firmly fixed, the depth of the trephine must be carefully and constantly explored with toothpick or probe, so as to see whether the section is nearly completed or not, and the instrument should now be moved in a most gentle and delicate manner in order to prevent the dura mater being suddenly wounded. When the section is complete the circular piece of bone is removed and the elevator is then applied, taking care to use the finger as a fulcrum, *not* the edge of the wound. All loose fragments of bone, bullets, foreign bodies, extravasated blood or pus must be removed, all hæmorrhage arrested, the edges of the wound brought evenly together with *plaster, not with sutures*, a pad of lint, cold water dressing, and a bandage applied; patient placed in a dark room, and kept in perfect quietness, completes the treatment.

The operation of trephining the skull may be called for in cases of compression due to—

1st. Depressed bone where elevation cannot be performed.

2nd. Extravasation of blood in linear or diffused fracture.

3rd. The formation of pus within the cranium, either sub-cranial or what is usually indicated by Pott's puffy tumour, where the vascular connection of the dura mater and the inner surface of the bone is interrupted and separated, intra-meningeal where the pus is situated in the cavity of the arachnoid or pia mater. Intra-cerebral where an abscess forms in the substance of the brain caused by the presence of foreign bodies, such as splinters of bone, bullets, &c.; or it may arise from direct injury, or after a fracture even without depression.

In fracture of the skull from bullet wounds, where the bullet itself, clothing, or other substances have been driven into the brain or too deeply into the soft tissues exterior to the cranium, if such foreign bodies can be easily seen and felt it is better to remove them, but if they cannot be felt or seen it is far wiser to leave them alone than have recourse to immediate operative interference, as suppuration will in all probability assist in removing such offending substances. Curious and heroic exploratory incisions for bullets and foreign matters may be far more detrimental to the patient's chance of recovery than the original injury itself. It is better for the surgeon to content himself here by doing too little than doing too much.

*Fracture of the Base of the Skull.*—This form of fracture is by far more serious than those of the vertex. It is generally caused by falling from a height on the vault or vertex, when the base generally fractures. This form of fracture is called by the French fracture by *contre-coup*, signifying that while the blow is received at one portion the fracture takes place at the opposite. Persons may sus-

tain such an injury by falling out of a window into an area, falling down a flight of stairs, or off a scaffolding. The patient when he is picked up may appear to suffer from shock and concussion, and may partially recover so as to converse with those about him, in fact, a person has been known to walk some distance to hospital while suffering from a most extensive fracture of the base produced by falling into the hold of a ship, and being in a very excited state the case was mistaken (for a short time), by the attending pupil for a case of semi-intoxication. In two days all the symptoms of compression set in and the man died on the third day after the injury, and a most extensive fracture of the base was found extending through all the cranial fossæ at both sides of the skull.

Therefore, in all head injuries with the history of a fall from a height pay the greatest attention to all matters of detail, and keep the patient at perfect rest, treat any symptoms that may arise, do not make a *hasty diagnosis*, and give a *most guarded prognosis*. It is sufficient for anxious inquirers to be told that all head injuries are necessarily dangerous, but some varieties need not to be despaired of. Rules are occasionally laid down by surgeons for specifying more particularly the exact seat of the fractures in the base by the signs and symptoms present. Such rules, I fear, are only approximately correct, however they may occasionally help one to form a diagnosis. If the fracture is confined to the *anterior cranial fossa*, the fissure extending through the orbital plate of the frontal and lesser wing of sphenoid, the signs are as follows:—Ecchymosis of the upper eyelid, sub-conjunctival extravasation, bleeding from the nose, and nearly all the symptoms of compression of the brain present either very soon after the injury or setting in in the course of a few hours, among which may be mentioned a hot, sweating skin, stertorous and whiffling breathing, slow and labouring pulse, dilated pupils, insensible to light, with more or less unconsciousness.

(To be continued.)

## THE ATTITUDE OF THE MEDICAL PROFESSION IN REGARD TO THE SIGNING OF CERTIFICATES FOR ASYLUM COMMITMENT, AND TO LUNACY LEGISLATION. (a)

By A. R. TURNBULL, M.B., Edin.,

Medical Superintendent of the Fife and Kinross District Asylum.

AMONG the powers entrusted to the registered and legally recognised members of our profession is that of giving certificates in cases of mental unsoundness. And though for each of us as individuals it is optional to use or not to use this power, yet I think I am warranted in saying that for the medical profession collectively the exercise of the power is not left optional, but is by implication laid upon us as an imperative duty, for the whole system of legislative measures which provide for the control and care of the insane, starts from the principle that the insanity shall first be duly attested by one or more medical men.

Medical certificates of mental soundness or unsoundness may be required for various purposes. Thus we may be called upon to give them in reference to testamentary capacity before the making of a will or before entering on important business engagements; for the appointment of curators to manage the property of a patient; in establishing the competence or non-competence of persons for pleading in courts of law, or the responsibility or irresponsibility of a person charged with crime, &c., but more especially the medical certificates form the basis of the legal action by which the insane are, when it is

(a) Read at a Meeting of the Fifeshire Medical Association at Dunfermline, on 1st May, 1885.

thought right, deprived for a longer or shorter time of their personal liberty and placed under asylum control; and it is to this special action that I wish more particularly to refer to-day.

In former times the custody of the lands of idiots or insane persons was invested in the king, whose duty it was to provide necessaries for the affected persons, and after their death to hand over the property to the rightful heirs. But there was no definite procedure required by law for ascertaining the insanity with the view of placing the person under control. It seems to have been left to those who were directly concerned with the patient to take any steps they thought necessary; and this must have been a very haphazard method. In 1744, by the Vagrant Act (England), two justices were authorised to secure any furious or dangerous lunatic, and order such to be locked up and, if necessary, chained. In 1774 it was for the first time enacted that a medical certificate should be given before the admission of a patient to a madhouse. Since that date various measures have been passed, dealing with asylums and the control of the insane; and in all of them it has been an essential principle that one or more medical certificates shall be required for the detention of every patient, whether private or pauper.

It is hardly necessary here to emphasise the principle which makes the existence of the insanity a question to be decided by trained medical opinion instead of by untrained lay opinion, as the right and proper one. Insanity is a *disease*, a derangement of certain structures and functions of the body, just as much as inflammation of the lung is, and is to be investigated on the same principles; and it differs from other diseases only in that it affects the social and legal relationships of the patient more profoundly than any other form of bodily disorder can do. He would be a bold man who would assert that the existence of inflammation of the lung can be ascertained as competently by the common sense of twelve laymen and a learned judge as by a skilled medical man; and yet the assertion so often made that the question of insanity is one for such lay judgment differs only in degree, not in principle, from the former absurd proposition. Now, too, that we are alive to the great importance of an early recognition of insanity, with a view to early treatment and the prevention of untoward results, the diagnosis of the disease is more than ever one for medical men.

It has lately been suggested that the power of giving certificates for asylum detention should be restricted in certain ways; that for example one of the two certificates required should be given by a public medical official appointed for a district, or that every case after being sent to the asylum should be visited within a certain time by such an official, and the continued detention be dependant on his ruling whether or not the patient is a proper subject for asylum control. It scarcely comes within the scope of the present paper to consider the advisability of such a change in the mode of procedure; and I shall, therefore, not dwell on it here further than to say that for my own part I believe the plan of certification or examination of every case by a public officer for the district would be found cumbersome in practice and disadvantageous in various ways, and that the present plan of having the certificates given by any two legally qualified medical men is preferable to it.

But the power thus entrusted to our profession of giving certificates for asylum committal, carries with it a very serious responsibility. Medical men have of late been frequently sued in the law courts for giving such certificates. Some have been found liable in heavy damages; and in other cases, though the action of the medical man has been justified, yet the necessity for defending the suit has entailed on him very serious expenditure. It is not a new thing to have such prosecutions, for there were instances of such actions in 1849 and 1862; but they have been much more numerous of late. Naturally there has been much feeling roused in the profession; and as there

is the possibility that any person who has been certified may afterwards bring an action at law and involve the doctor in the expense of defending the suit, even when the insanity and the necessity for control at the time were not doubtful, many medical men are now inclined to refuse ever to give any certificate of lunacy.

These recent lawsuits have also been the occasion of some strong remarks by English judges on the looseness of procedure in lunacy committals, and on the dangerous facility with which any person may be deprived of his liberty and immured in an asylum. For some years past there has been a considerable feeling in England that the Lunacy Statutes were defective in various points. It has been alleged that cases occurred in which asylum detention was prolonged after the necessity for it had passed away, though the report of Mr. Dillwyn's Parliamentary Committee of 1877 states that in the evidence brought before them such unwarranted detention had not been proved in any case. The recent proceedings in the law courts have again stirred popular attention in the matter; and further legislation has been called for. In March of this year a bill was introduced by the Lord Chancellor in the House of Lords for the amendment of the Lunacy Acts. This measure will affect the position of the profession in England in regard to lunacy proceedings; and as our position in the matter, and the legal responsibility incurred by us in signing lunacy certificates, must be of interest to us all, I have ventured to bring the subject before you for discussion to-day. There can, I think, be no doubt that the profession ought to have clear views on the subject, and should exert its influence to secure that the legislation on a matter so intimately affecting our patients and us should be put on a sound and practical basis, in the interests of our patients, ourselves, and the state in general.

In lunacy, as in other diseases, the interests of the patient call for early recognition and early treatment of the disorder, and for the adoption of measures which will as far as possible save the patient from the hurtful consequences of his disease. In some instances it is possible to treat the patient satisfactorily at home, without any appearance of restraint or interference with liberty more than in the case of any ordinary illness. But more frequently the loss of self-control and the irrational actions which spring from the mental unsoundness, causing danger to the patient and to others, make it necessary to restrict his personal liberty, to remove him from home and place him under asylum control; and when this is required, the sooner it is done the better for the patient and everybody connected with him. Early treatment then, early control if necessary, are essential in the interests of the patient. It must devolve upon the medical attendant to advise when such special control is required, and to give his aid in carrying out the measures for securing it; and he should be duly protected in the discharge of his duty. And in the interests of the State there should be such regulations as will reduce to a minimum the possibility of using the power of asylum committal in any unnecessary and improper way. The legislation dealing with the committal of patients to asylums should, therefore, be based on the following principles:—

1. For the sake of the patient the procedure should be as simple and expeditious as possible.
2. There should be such safeguards as will prevent abuse of the power of committal.
3. As the State requires medical men to act in the matter, it should give them due protection in their conscientious discharge of the duty laid upon them.

Let us see how far these principles are carried out at the present time.

1. *Simplicity and Expedition.*—There is some difference between the procedure for asylum committal in Scotland and in England. In Scotland, for every case, whether private or pauper, it is necessary to have a petition, statement, two medical certificates, and sheriff's order. The petition is addressed to the sheriff, and asks authority for patient's detention in an asylum. In the

case of a pauper patient it is signed by the inspector of poor; for a private patient it is signed usually by a relative or guardian, and it is necessary to state the relationship in which the petitioner stands to the patient. The statement gives a number of particulars regarding the patient and his illness, and must be signed by the person who signs the petition. The petition, statement, and two medical certificates are together laid before the sheriff; and he signs an order which authorises patient's transmission to and reception into the asylum. By the use of a special medical certificate, called the certificate of emergency, the patient can be detained in the asylum for three days without a sheriff's order. This permits of immediate treatment in urgent cases, and obviates the short delay incurred in getting the sheriff's order.

In England, for a private patient an order, statement, and two medical certificates are required. The "order" is more properly a "request for admission" addressed to the superintendent of the asylum; and on receiving this order, along with the statement and two medical certificates, the superintendent can admit the patient. The order can be signed by any one who has seen the patient within one month previously, and who is ready to affirm that the patient is a person of unsound mind. (It thus corresponds to the petition, and is quite different from the sheriff's order, of the Scotch procedure.) In the case of a pauper, the patient must be taken before or visited by a justice of the peace, who calls a medical man to his aid. If the medical certificate is given, the justice, on being satisfied that the pauper is a lunatic, makes the necessary order for his admission to the asylum. If the pauper cannot be seen by a justice of the peace, an officiating clergyman and the relieving officer or overseer may visit him, and their joint order authorises the removal to the asylum after the medical certificate has been signed. A statement signed by the relieving officer or overseer accompanies the order. Thus for a pauper lunatic only one medical certificate is usually required. If two certificates are produced, the justice has then no option, but must sign the order.

The new Bill for England proposes to enact that for pauper patients the order from an officiating clergyman and the relieving officer or overseer shall not any longer be valid for asylum committal. Hence all pauper lunatics must in future be examined by a justice of the peace, and committed on his order. In the case of private patients a petition (signed by a relative if possible) must be presented, along with the statement and two medical certificates, to a judge of county court, stipendiary magistrate, or justice of the peace, having jurisdiction in the place where the lunatic is; and the judge, magistrate, or justice shall give the necessary order after having satisfied himself that the evidence adduced is sufficient to warrant it. Provision is made for temporary asylum detention under an urgency order, until the permanent order can be obtained.

In all these modes of procedure the written opinion of one or more medical men that the case is a proper one for asylum treatment is an essential part. This is as it ought to be. So far as simplicity and expedition are concerned, the present English practice for private patients would seem to be best adapted for securing early treatment of the patient. But the intervention of the sheriff in Scotland is not found in practice to cause any prejudicial delay in securing treatment, or any unnecessary publicity in the proceedings; and when we come to consider the attainment of the other principles which have been laid down, we shall find that his intervention is of great service. The proposal to make the future procedure for private patients in England more like the Scotch procedure, by requiring a magistrate's order, is therefore, I think, judicious and wise.

It is important to point out that in the proposed new English procedure for private cases, and in the Scotch procedure for both private and pauper cases, the patient is not examined personally by any one except the medical men who give the certificates. The existence of the

insanity and the propriety of asylum treatment are left to the doctors for decision, and properly so; and the magistrate or sheriff gives his order on consideration of the documentary evidence submitted to him.

But the procedure for English pauper lunatics is not on the same footing. Though one medical certificate is given, the justice has to examine the patient personally, and satisfy himself of the insanity before he grants his order. Here a vicious principle is introduced, for lay opinion is brought in to decide a question that ought properly to be left to trained medical examination. If the lunacy is so striking as to be readily detected by the lay observer, no harm may be done. But if the case is at all a doubtful or difficult one, the justice may not be able to recognise the insanity, and then one of two things follows. Either in deference to the medical certificate the justice sinks his own opinion, and signs the order without having satisfied himself of the patient's insanity, in which case his examination has become merely perfunctory, and the patient's fate is decided virtually by the opinion of one medical man, who has not been corroborated or corrected by any other skilled examiner. Or on the other hand, if the justice conscientiously refuses to give his order, much valuable time may be lost, much trouble caused, and in some cases great danger incurred. Instances of both results are not wanting. From the accounts which have appeared in the newspapers of the action brought in the case of Mr. Charles Hillman, of Lewes, it would appear that the justices considered their examination of the alleged lunatic to be of a purely formal character—they were content with looking at the patient through a glass door; and it has been urged that in so doing they only followed the use and wont of previous years. Again, not long ago a case occurred in which a nurse became insane, and was certified by the medical attendant; but the justice could not satisfy himself of the insanity, and refused the order for committal to the asylum until further inquiry could be made. The nurse had therefore to be permitted to return to her usual work; and before the following day she had placed a child on the fire and injured it very severely. Those who are familiar with alienistic work know well in what a large number of cases insanity may exist to a marked degree and be of such a nature as to require special control, while yet it cannot be detected by the untrained observer, because it is not accompanied by those striking characteristics which are popularly but erroneously supposed to be always present in lunacy. For pauper cases, then, it cannot be said that the procedure is simple and expeditious, and favourable to the interests of the patient; and it would, I think, be a very great improvement if the practice for paupers in England were made the same as for private patients, by requiring two medical certificates and a magistrate's order, just as in Scotland the procedure for the two classes is identical.

2. *Safeguards in the Procedure.*—The statutory form of the medical certificate is of importance in this connection. It requires a statement of opinion (1) that the person is insane, and (2) that he is a proper subject for asylum treatment, and (3) it requires a statement of the grounds on which this opinion has been formed. These grounds or reasons are arranged under two heads—(A) facts indicating insanity observed by the medical man himself, and (B) facts indicating insanity communicated to him by others. Every certificate must contain facts observed by the doctor; the facts communicated by others are useful as corroborative evidence, but are not essential. The third requirement of the certificate is very important, for a due compliance with it makes it almost impossible that the medical examination can be made in a careless or merely perfunctory way.

It is often asserted that under the present English statutes any person may be shut up in an asylum, if only some one will sign an order and get two medical certificates. This cannot be said in so many words in Scotland, for here the sheriff's concurrence is required. The new

Bill for England proposes to follow the line of the Scotch procedure by making a magistrate's order necessary.

The intervention of the magistrate is an important feature. We still see that the asylum committal can be carried out only with the sanction and co-operation of medical men; and it is virtually they who set the procedure in motion. But they are not, any more than any other unofficial citizen, authorised to interfere with the legal liberty of their fellow-subjects; and it is therefore much better that the actual warrant for asylum detention should come, not from them, but from a magistrate or official who has been duly entrusted by the State with the power of suspending the liberty of the subject when the public weal demands it.

Furthermore, the intervention of the magistrate may be made to supply a very efficient safeguard against the abuse of the power of asylum committal, if he acts in a judicial, not merely in a ministerial, capacity. On this point there is evidently much difference of opinion in our profession. Some of the medical papers urge that it is derogatory to the profession to have to submit its certificates to the inspection of a magistrate; and many medical men hold that it should be sufficient to state simply that the patient is insane and requires asylum treatment, without being required to give evidence in support of the opinion. But there is much to be said in favour of the opposite view. A case of crime and a case of lunacy are not parallel in any way except in that the person charged is to be deprived of his liberty. Now no one charged with crime, even if he were taken in the act, can be detained for any length of time without being brought before a magistrate, who ascertains that there is sufficient presumptive evidence of guilt to warrant his detention until he can be formally tried. Why should not the liberty of the alleged lunatic be safeguarded as much as that of the alleged criminal, by requiring evidence to be shown for the propriety of asylum detention?

Again, if the question of the insanity were being examined into in open court, the judge would not simply take the opinion of the medical witness that the person is insane, and allow him to leave the box. He would naturally go further, and ask on what grounds the opinion had been formed, and would expect the witness to be able to point out the features in the person's conduct and conversation that show him to be insane; and in this way he would get a statement of facts sufficient to give the presumption that the diagnosis of insanity is well founded. In our customary lunacy procedure the patient is for the sake of his own interests not examined personally in court, and the evidence is received in written form, in affidavits as it were, instead of being taken orally; but there should be the same care in dealing with it as in the examination in open court. According to the doctor's skill in detecting and pointing out the indications of the mental unsoundness will naturally be the value attached to his verdict of insanity. If, for instance, he can bring out a definite delusion and show that it affects the patient's conduct and makes it irrational, his opinion will practically decide the question. If, on the other hand, a doctor were to state in court that a certain person is insane, and in support of his opinion could only allege the fact that the person wagged his head, he need hardly be surprised if the judge were to rule that very little, if any, weight could be given to an opinion put forward on such insufficient grounds. Why should the very same evidence, when given in a certificate, be accepted as valid and sufficient, as it must be if the intervention of the magistrate in a judicial capacity is not permitted? Common sense tells us that insanity was never yet diagnosed from wagging of the head alone, and that the doctor must have had other grounds for concluding that the person is a lunatic. He may find it exceedingly difficult to express these grounds in writing; but in omitting to do so he has failed to comply with the third requirement of the statutory certificate, and therefore his certificate is invalid and ought to be refused.

It must be clearly kept in mind that the magistrate is not here asked to pronounce directly on the insanity or on the propriety of asylum treatment. That is left to the medical men. The magistrate has simply to deal with the evidence incorporated in the certificates, and has to consider whether that is sufficient to warrant him in accepting the doctor's opinion without further inquiry, and in giving his sanction for asylum committal. It is of course, impossible to indicate by a hard-and-fast line what amount of evidence should constitute sufficiency. It must be left to the discretion of the magistrate, just as it is left to the discretion of the doctor to decide what amount of insanity constitutes fitness for asylum treatment; but it may safely be said that here law and common-sense should be identical. Those to whom it is proposed to submit the certificates have been trained to deal impartially with evidence, and it is altogether unlikely that they would use their discretionary power in any such way as would injudiciously or unjustly hamper the action of medical men.

No medical man considers it derogatory to give expert evidence in a court of law. Similarly, there is nothing derogatory in submitting the certificate to the inspection of the magistrate, especially as the certificate is nothing more or less than written expert evidence. Public opinion calls for due safeguards in lunacy procedure, and so long as the interests of our patients and the honour of our profession do not suffer, we are scarcely warranted in resisting the imposition of these safeguards. Another argument in favour of the introduction of the magistrate, as we shall afterwards see, is that it gives protection to medical men in their signing of lunacy certificates.

(To be concluded in our next.)

## HISTORY OF THE PROGRESS OF LARYNGOLOGY FROM THE EARLIEST TIMES TO THE PRESENT.

By GORDON HOLMES, M.D.,

Physician to the Municipal Throat and Ear Infirmary, London; Consulting Physician to the Sheffield Ear and Throat Hospital.

Il importe beaucoup de connaître l'histoire de la science à laquelle on s'attache.—Boerhaave.

### EPOCH I.—THE PRE-LARYNGOSCOPIC AGE.

(Continued from page 123.)

DURING the years 1747-48 an epidemic of angina raged at Cremona, mostly attacking children, many of whom undoubtedly suffered from croup. Martino Ghisi, of that city gave at the time a good account (1) of this disease, which is barely suggested by the descriptions of previous writers, (2) as he then observed it. In one case he saw the false membrane expectorated in the form of a cast of a trachea and bronchi; in another he inspected it *in situ* on opening the windpipe. Ghisi's essay, however, long remained in obscurity and was only unearthed after the attention of the profession had been universally roused by the next author.

In 1765 Dr. Francis Home, of Edinburgh, published a little work (3) in which croup is pictured in its full features. Twelve instances are given and the peculiar crowing voice, whence probably the disease was named by popular onomatopoeia, is prominently mentioned. Several autopsies were obtained. In the first case so examined Home remarks:—"To my great surprise the whole superior internal surface of the trachea was covered with a soft, thick preter-natural coat or membrane, easily separable from it, and generally lying loose upon it, and purulent matter lodged below and round it. "This condition was continued into the ramifications of the bronchial tubes. The subjacent parts were red, but there was no great degree of inflammation."

*Treatment.*—In this period the therapeutics of laryngeal disease show little or sensible advance. It may be noted, however, that the value of mercury (originally introduced into medicine by the Arabians as a skin remedy) in syphilis

was recognised in the fourteenth century, and it was extensively used by Fallopius and others as a specific in that disease.

The operative treatment of kyanche progressed steadily throughout this period, and was almost brought to perfection in the eighteenth century. Amongst the most primitive group of modern surgeons in the thirteenth and fourteenth centuries for the relief of cases in which a deep-seated abscess of the larynx seemed to threaten suffocation. Thus, Rolandi directs the practitioner to tie a string to a piece of hard-boiled flesh and let the patient swallow the morsel to a certain distance. The operator then drags it up again by the string with such force as may be likely to burst the abscess. Rolandi gives no clue to the surgical method to which he alludes for curing the laryngeal growth called *folium*. We may suppose, however, that the vulsellam recommended by Otius (4) and other ancient writers for extracting fish spines and other foreign bodies from the tonsils would be employed.

Lanfranc (5) describes a severe case of kyanche in a female who appeared on the point of suffocation after many days' illness. Diagnosing an abscess in or near the larynx, he made an incision "between the chin and the larynx," when some matter was discharged and the dyspnoea relieved. Subsequently it was found that the necessary food in liquid form could not be swallowed properly, but issued in great part from the wound. Feeding by means of a pipe passed down the pharynx was then resorted to and recovery ultimately ensued.

Pietro de Albano (1350-1316), one of the earliest occupants of the chair of medicine at Padua, is the first of the moderns to mention laryngotomy, and he devotes a considerable space (6) to arguing the propriety of performing it, ranging the opinions of preceding writers over against each other with a view to reconcile contradictions. He calls the operation *subocamatio* (from the Italian word *ocannare*, to cut the throat, commit suicide, &c.), a name which was used colloquially for centuries afterwards. His essay is a purely literary one, and he has no experiences of his own to offer.

Guido de Cauliaco (7) is the only other author who, previous to the sixteenth century, alludes to laryngotomy. He gives a brief account of it taken from the Arabic writers, but has evidently no personal knowledge of the operation.

Antonio Benivieni, of Florence (1440-1502), recounts (8) a case almost identical with that of Lanfranc, but occurring in a male patient. When death by suffocation from a deep-seated abscess without visible signs seemed imminent, he made an incision "in the upper region, under the very jaws, and also above the neck; and, when much sanies had rushed out, the disease was so much ameliorated that both breath and food were taken by the fauces, &c." This case is often quoted as the first known occasion on which the windpipe was actually opened, a distinction to which it evidently has no claim. (9)

We now come to a real instance of laryngotomy, the first recorded in direct terms, and not improbably the first instance in which the operation was really put in practice. Antonio Musa Brasavola, (1490?-1554?), professor of philosophy at Ferrara, dared this, to him at least, unprecedented procedure in surgery, and thus describes (10) the signal event:—"When there is no other place by which we can supply air to the heart itself . . . it is necessary to incise the throat under the abscess, so that through the foramen air may be taken and expired. We, with these hands, the sacred master barber not daring, made an incision in one who was on the point of death, and he was restored to health. This matter seemed so arduous to the most illustrious Alphonso III., Duke of Ferrara, that he thought it worthy of him to visit the patient and see the foramen."

Many decades, however, passed before the surgeons of the period became courageous enough to follow the example of Brasavola. In such cases the usual practice was to attempt giving exit to the matter by cautiously pushing a curved knife downwards towards the larynx. Hollerius (11) advises the use of a wooden one. Ambrose Paré (1509-1590), court physician at Paris, figures (12) a metal one, which resembles a modern sharp-pointed bistoury, but is about the size of a small table-knife. Paré, however, as is well known, was a bold surgeon, and he not only recommends laryngotomy, but he is the first to state that the cartilaginous rings may be cut, as he had seen the parts heal well after the infliction of this injury in warfare, &c.

Fabricius bestowed much thought on laryngotomy, (13)

but he remarks that the surgeons of his time, "being terrified" by the more or less pronounced disapproval of so many of the Greeks, Latins, and Arabians, "dared not to undertake the operation." "And I," he pursues, "following their footsteps have never performed it." Nevertheless, through his natural ingenuity and knowledge of anatomy he devised some improvements in the method of executing it. Thus, he shows that the incision through the superficial structures had best be vertical in order to avoid wounding any vessels, nerves, &c., and he directs that the proposed position of the cut should be first marked with ink. He also counsels the application of hæmostatics to the wound so that all bleeding may have ceased before the trachea is opened. Further he is the first to advise the introduction of a canula, a straight one with wings externally, and of such length as not to touch the posterior wall of the trachea for fear of causing pain and cough. He considers that this tube may remain in for three or four days, and also recommends (14) its use in cases of cut throat.

Casseri is another who modifies (15) laryngotomy from theoretical considerations. In his directions he seems to follow Fabricius, though he makes not the least reference to him in his work on the larynx. He shows the stages of the operation and the instruments required in a series of realistic figures. A double-edged pointed knife, like a dagger, is pictured for penetrating or stabbing between the third and fourth rings of the trachea. A canula appears, one of his own invention, which approaches in form that now used. This tube has a collar or projecting edge with holes on each side to receive strings to be tied round the neck, and it is bent rather abruptly at an obtuse angle (about 115°). The obliquely vertical portion tapers slightly towards the point where it is perforated by a small hole, and the sides adjacent are pierced by six or eight other such holes.

The second person who, as far as literary records go, is known to have opened the windpipe is Sanctorius Sanctorius (1561-1636), practitioner at Venice and professor of medicine at Padua. "He perforated the trachea between the third and fourth rings with the instrument (16) he used for drawing the water under the umbilicus of dropsical persons without pain, and he kept it in for two days." (17) The patient made a good recovery.

We next meet with Nicolas Habicot (18) of Paris, (1650?-1624), civil and military surgeon, attached to the Hotel Dieu. Being naturally dissatisfied with the long incorrect term *laryngotomy*, he renamed the operation *bronchotomy*, from *bronchus*, the ordinary word for the windpipe in the Greek writers. In the first two decades of the seventeenth century he performed bronchotomy three times: in the case of a boy, who, for fear of being robbed, tried to swallow a package of money, which became jammed in the pharynx; of a female who received a bullet in the larynx, and of a boy stabbed in and near the windpipe. All the cases recovered. Habicot made a crucial incision on the trachea, which he opened in thin persons between the second and third rings, and in fat subjects a space lower down. He used a short, straight tube, like that of Fabricius, which he represents with a small hole at the rounded inner end, and a slit underneath. He placed a band of "woven material" over it externally "to break the quality of the air," that is, to act as a respirator.

After the date of Habicot bronchotomy may be regarded as having attained the position of a standard operation, and it would be easy to produce a score or two names of surgeons, who described, advised, or performed it during the succeeding fifty years. No more space need, therefore, be occupied in distinguishing this array of authors and practitioners, and henceforth I shall only mention such surgeons as materially modified, improved, or extended the use of bronchotomy.

In 1673 Frederick Dekkers, professor of medicine at Leyden, proposed (19) to open the trachea with a trocar, and canula, and invented an instrument for the purpose. He hoped that this abbreviated method would so facilitate the operation that the most timid practitioner would not hesitate to perform it. Nevertheless his plan has only found favour in some special emergency, and surgeons have almost always evinced their preference for slow and deliberate dissection of the parts, so as to be fully aware of the structures incised.

In 1714 George Detharding, professor of medicine at the Hague, suggested (20) bronchotomy in cases of apparent drowning, on the supposition, now refuted, that a spasmodic

closure of the larynx by depression of the epiglottis or otherwise was the chief cause of suspended respiration. No examples are reported in which the proposal was carried out.

Laurence Heister (1683-1758), professor of surgery, &c., at Altorf, afterwards at Helmstadt is the author of the first complete and systematic text-book of surgery. (21) His work was translated (22) into all the languages of civilised Europe, and held its sway amongst schools and practitioners as the highest authority during the greater part of the last century. Heister gives a full and clear account of *tracheotomy*, (23) a name he devised as more correct than bronchotomy, which he thinks must be associated with the bronchial tubes. (24) He gives the details of a case of his own, and mentions three methods of operating, viz., the ordinary one of the period, that of Dekker, and by simply thrusting a scalpel direct into the trachea and then inserting a tube. Heister is the first to include division of one or more rings of the trachea in his description. He adopted this procedure, but does not claim it as his own innovation. He and his contemporaries seem to recognise only the short, straight canula, which was sometimes a little flattened so as to be slipped in more readily. With respect to the estimation in which tracheotomy was held in his time, Heister observes:—I am not altogether ignorant that many physicians are adverse to this operation, either esteeming it dangerous, deadly, or inhumane; but those gentlemen are greatly mistaken . . . . those are both ignorant and timorous who rashly neglect this safe, easy, and often salutary operation," &c. This very decisive opinion, so widely disseminated owing to the great popularity of Heister's text-book, must have rendered impossible the growth of opposition in the rising generation; and when we find Boerhaave and his *alter ego*, Van Swieten, counselling bronchotomy as the orthodox course in suffocative kyanche, it is evident that opponents could scarcely come forward after this time without being accused of irrational prejudice.

In 1730 it was first suggested to use a double canula. The operation had been successfully performed for suffocative laryngitis in a youth by George Martin, of St. Andrew's, and it was found very distressing to the patient to have the tube taken out frequently to clear it of the constantly collecting mucus. Hence the operator remarks (26), "I cannot but think it an ingenious proposal of one of our ministers here to make the pipe double, or one within the other, that the innermost might safely and easily be taken out and cleansed when necessary without any molestation to the patient."

In 1745 Morgagni drew attention (27) to the situation, previously ignored, of the isthmus of the thyroid gland below the cricoid cartilage, and sometimes covering the greater part of the trachea, so that the operator in tracheotomy might be prepared to meet this obstruction, and move it out of the way.

Home (28) recommended that tracheotomy should be tried in croup, in order that the removal of the false membrane might be attempted through the artificial opening.

#### FIFTH PERIOD.—From the Death of Morgagni to the Introduction of the Laryngoscope.—1771 to 1858.

The ample materials brought to light by Morgagni, Ferrein, and other investigators of the last period, would almost suffice to construct the science of laryngology, but the crude mass demanded a large amount of inference and verification before it could be accepted as final, and reduced to such form and order as would render it available for clinical practice. To this task the period we are entering was for the most part devoted, for, in fact, there remained but little in the way of absolute discovery to reward fresh researches in connection with the larynx. But while the growing importance of laryngology attracted a yearly increasing number of observers, the efforts put forth did not always tend manifestly to advance the topics treated of; views of a retrograde character, especially in physiology, were sometimes brought forward with the greatest sincerity, and new-born truths were often obscured by the specious reasoning of prejudiced or short-sighted opponents. The enumeration alone of all the authors in the domain of laryngology would occupy several pages, and, amidst the wide entanglement of proposition, objection, and mere verbosity, it is often extremely difficult to discern, pursue, and at length to extricate the slender thread of progress.

*Anatomy.*—The anatomy of the larynx being almost complete, with the exception of certain details not easily demonstrable, and more or less in the region of conjecture, we shall not find much further work worth recording under this heading.

About 1780, H. A. Wrisberg, professor of anatomy at Gottingen, relegated the small bodies called "arytænoid glands, by Morgagni, to the class of cartilages." He states, (29) "I have thought for some years that two new cartilages or corpuscles, similar to cartilages, should be reckoned during the parts of the larynx." Describing their position in the ary-epiglottic fold he gives them the name of "cuneiform" or wedge-shaped. He appears unaware of Morgagni's views, as to their nature.

The determination of the veritable distribution of the laryngeal nerves, scarcely indeed finally settled, engaged the attention of more than one anatomist. In 1791 the description of some of the cranial nerves, by C. S. Andersch (30), a pupil of Haller, were published. The dissections of the nerves of the larynx were by far the most perfect yet made, nor have they since been surpassed. Here for the first time is pointed out the branch given by the recurrents to the ary-tænoid muscle. He attributes no muscular branches to the superior laryngeal nerve, except that the crico-thyroid, and traces most of its filaments, even after they have penetrated muscles, to the mucous membrane.

Very perfect dissections of the nerves were also made in this period by Joseph Swan (31), of London, about 1830. Amongst the rest he displays the laryngeal nerves, from different points of view, in several large and well finished lithographs with a minuteness and accuracy never before attempted.

In 1828, C. Mayer (32) noted the existence of two fibro-cartilaginous nodules (now called the anterior sesamoid cartilages) of an ovoid shape, about half a line in length, embedded in the ends of the vocal bands at their attachment to the thyroid cartilage.

The existence of an epithelium on mucous and other internal membranes was doubted until 1838, when Jacob Henle (33), then professor of anatomy at Zurich, as a result of the advance in the construction of microscopes, proved that it is the invariable covering for all surfaces of the body. He made three kinds of epithelium, viz., pavement, cylindrical and ciliated, that of the larynx belonging to the last class, which is the same as the cylindrical with the addition of cilia. He states (35) that these are most evident in the larynx on the anterior wall, whilst on the posterior wall and sides they only commence immediately above the superior vocal ligaments. As Henle remarks, however, the cilia in the respiratory tract had been previously noticed by Valentin and Parkinje.

(1) Guillaume de Ballon or Ballonius is vaguely stated by some authors to have described croup in obvious terms as early as 1578 in connection with pertussis. On searching his works, however, I find nothing more pregnant than the following sentence:—"Others (i.e. of those attacked by *quinta* or pertussis) died with great difficulty of breathing, and at that terrible and irremediable" (*Epilemorium et Ephemeridium* L. II., Ostiva, 1578, Opera Quina, Venetia, 1734, T. I., p. 157 *et seq.*).

## Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND.

SURGICAL SECTION.

MEETING HELD FRIDAY, MAY 22ND.

The President, Dr. E. H. BENNETT, in the Chair.

### TREATMENT OF STRICTURE BY INTERNAL URETHROTOMY.

MR. THORNLEY STOKER read a paper on the treatment of stricture by internal urethrotomy. He advocated the more frequent use of that operation in cases of well-established organic stricture, where recurrence took place after gradual dilatation, where that treatment could not be borne owing to the irritation it set up, or where the circumstances of the patient demanded speedy relief. He stated that in 1871, when he became a hospital surgeon, the practice in Dublin leaned to the use of the so-called immediate dilatation in those cases where rapid treatment was determined on; but that, since then, the use of urethrotomy had become more general, and he believed bursting to have been practically abandoned by Dublin surgeons, and that he made his communication to the Academy to mark a local epoch in treatment. He had burst 18 strictures in his earlier practice, and had been so impressed, both by his own cases and by those of other surgeons, with the liability to rapid recurrence after this operation, that he had relinquished it in favour of urethrotomy. Mr. Thornley Stoker mentioned that he had out 25 cases with Maisonneuve's instrument, and in no instance had a bad result or cause for grave anxiety, except in one case, where somewhat severe hæmorrhage took place and required the retention of a large catheter in the urethra. He gave his reasons for preferring urethrotomy done from before backwards, after the fashion of Maisonneuve, and recommended the incision to be made in the roof of the urethra. He argued that a catheter should not be retained in the passage after the operation unless hæmorrhage took place. On this latter point he placed much stress, and attributed to its observance the freedom he had found, in all his latter cases, from rigors and inflammatory trouble; while in some earlier ones which he referred to, the retention of a catheter had, in his opinion, been the cause of such mischief.

The PRESIDENT believed most surgeons would concur in Mr. Stoker's opinion that internal urethrotomy should replace the forcible laceration of the urethra. For his own part, he would not incur the risk of dealing with stricture by forcible rupture. He inquired the grounds upon which Mr. Stoker preferred the section on the pubic side of the urethra to that on the floor of the urethra—in other words, his reasons for

asserting the upper tissues were healthy, while the lower were diseased. One of the advantages of Civiale's instrument was that the surgeon could divide with it either above or below.

Dr. BARTON regarded the subject as having special interest since his early days, when he had the benefit of the teaching of Hutton, who was a skilful director of the catheter, and conducted all operations of the urethra with elegance and precision. Contrary to Mr. Stoker's view that gradual dilatation was a temporary measure, and in the ultimate result unsatisfactory, his own experience was that it was the best treatment, if it could be adopted; and year by year, as he treated more difficult cases, he found its scope and range greater than he at first supposed. Indeed, he was convinced there was but a limited number of cases that could not be treated by gradual dilatation, if only the surgeon possessed patience as well as dexterity. The patient and gentle use of the bougie and catheter would overcome almost all the complications which the disease presented; and as to the ultimate result, he believed that if the treatment were carried sufficiently far, it would leave as permanent a result as any other means yet discovered. In the case of a gentleman who returned to this country after ten years' absence, he passed a No. 8 instrument easily; and in the case of a medical gentleman whom he treated for a very tight stricture, he found it remained perfectly open after six years. Therefore, gradual dilatation gave as great an amount of permanence as any other method, and internal urethrotomy would not give as good. Again, despite Mr. Stoker's remark that internal urethrotomy was not a dangerous procedure, he had seen fatal results follow. He agreed, however, that that method gave more rapid results, but not more permanent. There were cases in which gradual dilatation could not be adopted, and in which the surgeon had to choose between bursting and internal urethrotomy. His choice in such cases would be in favour of internal urethrotomy. Both were open to risk, and could not be compared with dilatation. Again, there were other cases requiring external urethrotomy. In every case, before selecting any other method of treatment the surgeon should sedulously, carefully, and tenderly try gradual dilatation.

Mr. STOKES said the subject was one which for a number of years had engaged his attention. In 1864 he introduced into Dublin Maisonneuve's operation, which he had learnt from the distinguished French surgeon himself. Although Mr. Stoker was apparently unaware of the fact, he had published papers in the *Medical Press*, the *Dublin Medical Journal*, the *British Medical Journal*, and other periodicals, in which he fairly put forward the alleged advantages of that operation. Speaking from an experience of sixty-seven cases during the past twenty-one years, although his opinion of the operation was still very high, he did not think it should be looked upon in the light of Mr. Stoker's paper as a royal road to the cure of urethral stricture. But he agreed with Dr. Barton that the chances of recurrence of the disease were not greater after the older and safer treatment of gradual dilatation. Mr. Stokes also thought it better to retain a catheter in the urethra for some time after the operation, otherwise the recurrence of the stricture was, as a rule, rapid. That was also the opinion of Maisonneuve. In reference to the mode of division, he agreed with Mr. Stoker in thinking the upper wall of the urethra was the best to be divided, not only for the reasons he put forward, but also those of Maisonneuve, that there was much less danger of any lodgment in the urethra, or any infiltration taking place after the operation, when the upper wall was divided than when the lower one was. By passing in a large well-oiled bougie immediately afterwards the sides of the wound were dilated, assuming a triangular or conical form, with its base below and apex above. This became filled with lymph, and a wedge-shaped cicatrix formed, which was not at all so likely to take place if the wound was allowed to close after the division of the stricture. Notwithstanding the favourable results he had had, out of the sixty-seven cases there were only ten in which he was able, after a considerable period, to determine that no recurrence of the stricture had taken place. He had performed the operation on the same individual twice, and yet there was a recurrence of the stricture, which he subsequently treated by gradual dilatation. He believed with Mr. Barton that although dilatation was the most tedious, it was certainly the safest method; and he also agreed with him, with Hutton, and Prof. Smith, in maintaining that there was a

better chance of absorption of the new material by the steady, continuous, gradual pressure caused by the frequent introduction of the instrument than by any cutting operation whatever. It was dangerous to advocate the operation of internal urethrotomy to the exclusion of the slower and safer method of gradual dilatation. But he certainly endorsed Mr. Stoker's observation in reference to the great superiority of internal division over the immediate dilatation of Perrève or Holt, done with the instrument devised by the late esteemed secretary of the Surgical Society, Mr. Richardson. In his communications he had given his reasons for considering the internal division of the stricture superior and more scientific than the rude tearing open of the urethral stricture—a method which gave rise necessarily to a lacerated wound in the urethra, the length, depth, and extent of which the surgeon knew not.

Mr. ORMSBY observed that Mr. Stoker deserved thanks for bringing before the Section such a practical subject. He had himself performed all the operations described—the gradual dilatation, the forced, the internal urethrotomy, and the external. The treatment depended more on the patient than on the stricture, some being suitable for one and some for another method. Every surgeon agreed that gradual dilatation, where it could be performed, was the best method. But if the patient wanted to have the treatment carried out rapidly and efficiently, internal urethrotomy with Maisonneuve's instrument afforded the best result. Mr. M. Colles had stated that all strictures were liable to return. As an instance, he mentioned, in his own practice, the case of a man who had had Holt's operation performed at one hospital, Richardson's at another, and at the Meath Maisonneuve's. It was, therefore, probable, no matter what method was adopted, that the stricture would recur if the patient did not take the precaution either of going at once to a surgeon, or providing himself with a bougie to pass occasionally. He agreed with Mr. Stokes as to the advantage ascribed to Maisonneuve's method, especially in preventing the urine coming into contact with the fresh cut surface. He performed the operation without an anæsthetic.

Dr. BALL pointed out that in the use of Maisonneuve's instrument there was danger of injuring other portions of the urethra by the sharp edge of the knife. He knew of a fatal case in which the *post mortem* examination showed that the entire length of the urethra, from the meatus to the bladder, was slit with the instrument, the wound being deepest in the healthy parts. That danger, however, was obviated by a modification invented by Teavan, of London—namely, a triangular sheath over the cutting edge.

Mr. CORLEY spoke from twenty-seven years' experience, since he was a pupil of the late Mr. Taggart, who was a thick and thin advocate of gradual dilatation as the safest method, and was so particular and careful that he would have the word "gentleness" inscribed on the handle of every catheter that the junior practitioner used. When he was first attached to Jervis Street Hospital division or bursting was fashionable; and though he never saw a fatal result from it, he knew that fatal results had occurred. The fact that a fatal result sometimes followed a particular operation he regarded as of little importance, since he knew it to occur following gradual dilatation; and Murray Bradwood's book gave, as a common sequence to passing the catheter, urethral fever, catheter fever, pyæmia, and septicæmia. For the same reason, he took exception to Mr. Stokes' caution about passing the catheter in the surgeon's study. When he came to the Richmond Hospital, he found the cutting operation which was introduced by Mr. Stokes most favoured. With his experience of the three methods, he had come seriously and fairly to the conclusion that the cutting operation, as done by Maisonneuve, was the best and safest, and obviated a number of inconveniences that certainly belonged to gradual dilatation. There were several cases met with in which a long period of trial occurred before getting in the catheter; for instance, one in the Richmond Hospital, given up as hopeless after six weeks, when Mr. Stokes succeeded in introducing a catheter. The cutting method was rapid for the patient, satisfactory to the surgeon, and as free from danger as any other.

Mr. THOMSON said the real question to decide was whether stricture was curable, or, rather, how near could they approach to the condition of getting rid of the possibility of its return. All the speakers agreed that strictures returned, whether the operation was one of cutting or of bursting, although some surgeons had invented appliances which they

claimed out the strictures so as to prevent their return. His own experience was that under all modes of treatment strictures returned. Hence the question was—What method of dealing with the stricture would give the best approximate result short of absolute cure? Mr. Stoker had been wrongly taken up. He did not advocate internal urethrotomy, or any other form of division of the stricture in all cases. The twenty-five cases of internal urethrotomy were not all the cases Mr. Stoker had treated, and he had certainly treated others by the gradual dilatation method. Therefore, Dr. Barton and Mr. Stoker were probably at one as to the merits of that treatment. There were cases capable of treatment by the gradual dilatation, and others which must be cut. Mr. Corley had stated an important point—that they were not to consider gradual dilatation as a method altogether free from risk. He had himself seen a patient who, on the introduction of a catheter, was seized with uræmic convulsions, and died of suppression of urine. The same happened after internal urethrotomy in a case of his own. Therefore, they were not to base objection to a line of treatment on the fact of a death occurring now and again. But the question was this—When the surgeon came to deal with a case of stricture, what method was the best for the patient; what gave the least risk; and what gave the best chance of staving off the evil day? In the great majority of cases dilatation was that method. It was essentially the least irritating, if properly carried out. By using a cutting instrument a severe wound was inflicted upon a very sensitive part, with the risk of setting up irritation of the sympathetic, which so often followed cutting operations. Hence the advantage of gradual dilatation. But there were cases in which no amount of gradual dilatation was satisfactory. The stricture might be dilated one day, but in a few days afterwards it would be found to have come back to the starting point. Again, when a catheter was introduced for the dilatation of the stricture, the patient was liable to be seized with rigors, there being great constitutional disturbance and the probability of catheter fever. There was another form of stricture which might be dealt with by urethrotomy, internal or external, as not usually yielding to gradual dilatation—namely, traumatic stricture. So, too, a case suffering from rigors after the bougie would be well treated by internal urethrotomy, no greater disturbance being caused than by the passing of the bougie. At the same time, he agreed with Dr. Barton, that for the majority of cases gradual dilatation was the method that ought to be adopted, and that questions of the mere convenience to the patient or the surgeon ought not to be taken into consideration where it was a question of a man's life whether a dilating bougie or a cutting instrument should be used. However, in discussing methods of cutting, he was entirely in favour of Maisonneuve's.

Mr. WHEELER, referring to Mr. Stoker's remarks that the reasons why in Dublin immediate dilatation was adhered to might be found in the revulsion of feeling against the earlier forms of urethrotomy, or to the possession of the late Mr. Richardson's modification of Holt's dilator, did not think that the instrument modified by that erudite surgeon either prevented or retarded the adoption of internal urethrotomy. He reminded Mr. Stoker that when a colleague of his some years ago, in the City of Dublin Hospital, he had performed internal division in two cases. There was no comparison in the cases suitable for Stoker's section, which the author referred to, and those suitable for internal urethrotomy. He took exception to the statement made on the authority of Sir Henry Thompson (whom he never quoted unless his own experience verified the treatment advocated) that the surgeon could not reach a series of strictures through perineal section; and as examples to the contrary, he took two cases out of many. A gentleman returned from the Cape had eight or nine urethral perineal fistulae, and was represented to have had Syme's operation performed on him in the colony; but the urethra had never been opened, while the scrotum, no doubt, had been split, and each testicle could be pulled away, one from the other, to the opposite thigh. Two of the strictures he divided by Syme's method on the staff, and the third on a director passed into it. He did not find any difficulty in treating these strictures through the perineum. In the second case four strictures existed, one being at the orifice from a traumatic cause. The patient had extravasation of urine; but without difficulty he treated the strictures through the perineum. Both cases made good recoveries. In the first

a No. 9 catheter was used by the patient, and in the second a No. 10 had been frequently passed. Although it might seem from the tenor of the paper the author advocated only one operation, yet Mr. Stoker had distinctly stated he did not wish it to be understood that he had relinquished gradual dilatation. There were some cases suitable for gradual dilatation, some for perineal section, some for internal urethrotomy, and some for the much-abused forcible dilatation. Recent cases were suitable for gradual dilatation, but old callous strictures were not. He could not concur in the statement that the return of contraction was more rapid after division than after internal division. When there was rapid contraction it was because there had not been sufficient dilatation by which the stricture would be fairly ruptured. He spoke from personal experience of the operation, having had several cases. Contraction did not recur more rapidly after this treatment than after internal urethrotomy, of which he also had experience, Civiale's operation being the one he performed. He agreed with Mr. Stoker that it was injurious to tie in a catheter. It was quite clear that gradual dilatation should be practised whenever possible, but the surgeon must select for himself the method most suitable in each case. He was not aware that a cicatrix was formed after Maisonneuve's operation, as had been stated, nor did he think a cicatrix would form after an internal urethrotomy, if properly cut. Contrary to the experience stated, he had himself dilated a traumatic stricture in a patient, a native of Roscommon, in the City of Dublin Hospital, into whom, on his admission, a No. 1 catheter could not be introduced, but who now passed a No. 8 for himself.

Dr. FALCONER suggested that a drug recently brought before the profession—namely, cocaine—should be injected into the urethra before operating, instead of placing the patient under an anæsthetic.

Mr. HAMILTON said Mr. Stoker had not removed from his mind two convictions impressed upon it by observation and practice—one, that a stricture once formed could never be removed; and the other, that far and away the vast majority of strictures were amenable to, and ought to be treated by, the process of gradual dilatation. He was in the habit of teaching his class, and telling the patients, that no matter what plan was adopted the stricture would return. His experience was, that he was able to proceed with gradual dilatation in ten days or a fortnight. The object was to get in an instrument first, no matter how small; and he maintained, with Syme, that there was no stricture through which a surgeon could not pass an instrument if he only had the patience and, above all things, gentleness. He always held and taught that blood on a catheter or bougie was a disgrace, as indicating that too much violence had been used. His practice was, when he got a puzzling case of stricture, to go on Sunday, and, kneeling on a soft pillow beside the patient's bed, make up his mind not to leave till he had passed the instrument, and very rarely had he failed. Having succeeded in passing in ever so small an instrument, he left it there for the night, and found that in the vast majority of cases it was no inconvenience if the patient was kept under the influence of small doses of opium. Next morning he found the instrument perfectly loose, and he could, without difficulty, pass in one a size or two larger. He then went on increasing it, size after size, but not too rapidly, so as not to set up rigor by too much disturbance, and finally, he gave Mr. Stoker's advice about the clock and catheter on Saturday night.

Mr. THOMSON asked that Mr. Wheeler, who seemed to dissent from Mr. Stokes' view as to the healing of a wound in an internal urethrotomy, should state how the wound did heal if a cicatrix was not formed.

Mr. WHEELER said he stated it as his opinion that it heals by means of healthy tissue. When the urethra was cut into, healthy tissue formed in the stricture already cut, but certainly not a cicatrix.

Mr. ORMSBY—What is it?

Mr. WHEELER—Healthy material; healthy tissue is produced.

The PRESIDENT—Do you mean to say the cicatrix is diseased material?

Mr. WHEELER—No; but I say it is material that would be likely to contract again. What I mean is, that it is not contractible cicatricial tissue that is produced.

Mr. THORNLEY STOKER replied. He said his paper read over again would answer most of the objections raised, and

therefore he would leave it to answer for itself. In reply to the President's question, he advocated the incision of the roof of the urethra in preference to the floor, because he considered he was cutting into healthier tissue. It was matter of observation to those who dissected diseased urethrae that the floor was much more frequently the seat of disease than the roof. That gradual dilatation was the safest method of treatment no man of common sense could for a moment deny, or that it was the method applicable to the greater number of organic strictures. But he contended that urethrotomy might be more generally practised than at present. He was familiar with Mr. Stokes' writings, and especially with his paper published in 1871; but he considered that internal urethrotomy was more advanced now than Mr. Stokes supposed. He denied having spoken lightly of the dangers of the operation, or that he operated off-hand in his study. What he did was after careful examination of the urethra—a procedure enjoined in Sir Henry Thompson's teaching. Dr. Ball had referred to a well-known case where the whole of the urethra was split up; but there was no operation that was not subject to accident, and the fact that there was only one record of the kind showed that urethrotomy was a comparatively safe operation. He could not follow Mr. Hamilton's practice his experience being that when an instrument was left in, troublesome rigor and uræmic fever were set up, and consequently he left continuous dilatation out of his practice altogether. The Section then adjourned.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, AUGUST 12, 1885.

SURGERY: PAST AND PRESENT.

THERE is always much to be learned from carefully instituted comparisons, not alone as affecting immediate

action, but especially also in the way of influencing further progress; and in the surgery of to-day there is to be found abundant evidence of the truth that its present proud position is to a great extent based upon the experiences and errors of the generations that have gone before. Too often is it rashly assumed that modern improvements are essentially the outcome of modern discoveries and research, and that they owe nothing or little to the cruder efforts of the older masters, whose names, however, are venerated in the annals of practice. Such estimates of comparative merit are, it must be admitted, rather the result of hasty generalisation than of mature reflection, and it is rarely that justice is not done to those whose labours must command respect when a calm and deliberate survey is taken of the work which was accomplished by those who "went before." It is always a matter for congratulation when an acknowledged master takes upon himself to paint the picture of the past side by side with the representation of the present as exemplified in his own teaching and experience; and in this connection the address delivered by Mr. Marshall before the British Medical Association at Cardiff possesses peculiar attractions, not merely on account of the personality of the author, although this gives it a very prominent interest, but also because of the unusually favourable opportunities for criticism enjoyed by Mr. Marshall, and utilised by him with a judgment as accurate as it is admirable.

The sketch of surgery forty years ago which the address contains cannot fail to show how, and in what direction progress has been since this time; it will not, moreover, diminish the feelings of respect with which we are accustomed to regard the achievements of men who worked under disadvantages barely conceivable to those whose acquaintance with the practice of surgery dates from the more recent years. Forty years ago, "injuries not involving a breach of the surface of the body, simple inflammations consecutive to these, or so-called local idiopathic inflammations, which came under the care of the surgeon, such as local sprains, simple dislocations, synovitis, orchitis, and other cases, were not less satisfactorily treated in 1844-5 than in 1883, and the progress of patients towards recovery was quite as rapid." As might be anticipated, however, the case is very different when suppurative, ulcerative, and gangrenous wounds are considered in the light of comparison; modern treatment offers unmeasurably better results than were obtained at a time when these lesions were regarded without reference to their preservation from the influence of septic particles. Again and again are we brought face to face with the marvellous change wrought in practice and in the result of practice, since the introduction of those scrupulous measures of cleanliness which, apart from controversy on special points, it has been the triumph of antiseptic surgery in its widest meaning to bring about; and in the unexaggerated and faithful comparison contained in Mr. Marshall's essay, is to be found the most conclusive evidence that could be afforded of the inestimable benefits that have flowed from a general recognition of the importance of absolute freedom from every kind and degree of impurity, in association with wounds.

Another instructive instance of the good that has ensued on a correction of errors, and of the treatment founded on them, is to be seen in the comparison between the mode of combating syphilis in 1844 and 1883. At the former period soft and hard sores were in no way distinguished, as far as their possible consequences were concerned; and mercury as a specific remedy was not recognised; while iodide of potassium was administered in doses varying from one to three grains, five grains being a maximum very seldom employed. It would, however, be unfair to base a judgment of the value of earlier surgery on the lack of understanding shown by its professors as to the singularly clear distinction between dangerous and simple venereal lesions; for contemporary science is not altogether free from confusion, or rather contemporary scientists are not wholly agreed, on the point; but it is unquestionable that so far as present modes of treatment are concerned, they show incalculable advance on the crude resorts exemplified in Mr. Marshall's retrospect. How far this advance owes its growth to mistakes of the past it is at once difficult and profitless to conjecture.

One of the most striking references in the course of the address is that relating to abdominal surgery and to an operation by Liston, in which he opened the abdomen and evacuated thirteen quarts of dark-coloured glutinous fluid from a large cyst. Ovariectomy had been denounced by Lister in 1840 as "an unjustifiable piece of butchery" and Mr. Marshall not unnaturally exclaims: "How all this has been changed by cautious, and, if I may coin a word, *precautious* surgery!"

#### THE ABOLITION OF POOR-LAW OFFICES IN IRELAND.

THE cessation of workhouse medical officers in Ireland to hold their appointments, which will result from the amalgamation of certain unions, has—as we have recently explained—been the subject of most anxious thought by those whose duty it is to protect the interests of those officers, and we are truly glad to be able to report to-day that the Irish Medical Association has succeeded in preserving to these officers all their rights to compensation, or to a continuance of their salaries, notwithstanding the abolition of their offices.

It will be recollected that, in stating the case, we laid down the following as representing our view of the law affecting these officers:—*First*, that *under no circumstances* can the guardians possess any power to dismiss any union officer above the grade of a porter. *Second*, that that power is vested solely in the Local Government Board, who are debarred by the Act from divesting themselves of it by any possible means. *Third*, that the Local Government Board have no power to dismiss a workhouse officer unless they "deem him unfit," or unless he refuses or omits to perform his duty; and that they must, in the exercise of this power, be prepared to satisfy a court of law that they have not deemed an officer unfit without sufficient cause. *Fourth*, that, inasmuch as the Act expressly carries forward all contracts made by the abolished board of guardians, and preserves the binding validity of such contracts, the amalgamation of unions

does not break the officer's contract, nor in any way deprive him of his rights.

Since we have put forward this interpretation of the law, the Irish Medical Association has taken the advice of the most eminent counsel who could be obtained—*i.e.*, the Solicitor-General, Mr. Monroe, Q.C., and Mr. Purcell, Q.C., County Court Judge for Limerick, upon queries substantially the same as those above expressed. The Association has been obliged to call upon its legal advisers because a Bill had been introduced by the Chief Secretary for Ireland and run through the House of Commons, which provided that the guardians *might if they thought fit* compensate officers for abolition of office in exactly the same terms as those upon which they may now grant pensions. This Bill was framed by the Irish Local Government Board with the kindly intention of saving to the abolished officers a possible compensation which, under existing law, the guardians had no power to grant; but it will be easily understood that the Irish Medical Association was not satisfied with a measure which left the officer at the mercy of the guardians. Being well aware that it would be quite impossible to get the assent of the Irish Party to a Bill which would bind the guardians to compensate, the Association was prepared to accept the measure as long as they were quite certain that it would not rob the officer of any rights which he might possess under existing law, and it was on this point that they consulted counsel. The answer given was, that though a discretionary Bill would not exactly repeal the existing law, it would offer such an obstacle to any officer in contending for his pre-existing rights that it would practically deprive him of those rights, and, thereupon, the Council at once determined to make an effort to add a saving clause to the Bill which would explicitly declare that pre-existing rights were to be in no respect altered by it. Some time was necessarily expended in obtaining the legal advice and arriving at this determination, and meanwhile the Bill had got through the Commons and through all its stages but one in the Lords, so that the modification of the measure was almost a forlorn hope. Nevertheless, at the solicitation of the Council of the Association, Dr. Jacob undertook to go to London and make the attempt, and—we are glad to say—his efforts have been crowned with success. His representations were received in the most considerate manner by Lord Waterford and the Attorney-General, who had charge of the Bill in the two Houses, by Lord Fitzgerald, the Earl of Milltown, and other peers, and by Mr. Cullinan, who had carriage of the Bill in the Irish office, and by their assent the saving clause was inserted in the Bill, and it has gone back to the Commons for approval, where we earnestly hope that no objection will be raised. In any case, the position of the Irish Poor-law officer will be rendered infinitely more secure by this change in the Bill, for, if it passes, he can apply to his guardians for compensation, and, if refused, can fall back on his original rights. If it does not pass, those rights will remain untouched, but what they amount to will have to be decided by the judgment of the highest court of law. If the advice which the Irish Medical Association has received be correct, the officer will continue to be entitled to his salary, notwithstanding the amalgamation

of his union, and he cannot be got rid of as long as he is "fit" and willing to do his duty. Against whom his claim will be binding, whether the ex-guardians of the abolished union or the guardians of the newly enlarged union, is not quite clear, but there can hardly be a doubt that some one must pay in respect of a contract for services, which contract is carefully preserved in force by the Acts of Parliament.

In thus protecting the rights of workhouse officers the Irish Medical Association has added one more to the many valuable services which it has rendered, and for which not only the gratitude, but the substantial support of the profession are eminently due.

#### THE POLITICAL HELPLESSNESS OF THE PROFESSION.

In the same number of the *British Medical Journal* in which we find recorded the assurance that the Association needs no political reorganisation, we find the following melancholy illustration of the utter helplessness and censurable sleepiness of that organisation:—"In the session of 1884 powers of requiring the compulsory notification of infectious disease were inserted into the York Improvement Bill of that year under very extraordinary circumstances. The corporation had not asked for these powers, and, of course, had not given any preliminary public notice with regard to them, as would appear, from the Standing Orders, to be requisite; but whilst the Bill was under discussion by the customary committee of the House, Mr. Hastings, one of the members of that Committee, and the introducer of a measure to make the notification of infectious disease compulsory throughout the country, happened to ask the promoters why they did not ask for such powers for York. The counsel in charge of the Bill seems to have been unprepared with any other answer than that they had not thought about it; and being anxious, no doubt, to please the Committee, he assented to the introduction into the Bill of Mr. Solater-Booth's model clauses of 1882. In this way the medical practitioners of York found themselves in the position of being liable, under penalty, to report to the sanitary authority all cases of infectious disease in their practice. The Town Council, though having powers of notification thrust upon them in this amazing manner, do not appear to have considered until lately whether they should exercise such powers; but they have now adopted a report" which puts every medical practitioner in York under the yoke of compulsory notification.

Was there ever such a confession of indifference and incompetence, if not worse, on the part of the Parliamentary Bills Committee, as this? We venture to ask, was that Committee aware that these notification penalties were being inserted into the York Bill in 1884? If not, what excuse have they to make for their ignorance of the fact? If they had knowledge of the proposed law, did they take the trouble to ascertain the views of the York practitioners on the subject? And, finally, what action did they take to stop the Bill?

We feel it our duty to warn the profession and the Association that they are being, and have been, sold to

the compulsory notificationists by the Parliamentary Bills Committee or whoever answers to that name. The Burgh Police (Scotland) Bill, which puts the whole of Scotland under the foot of the compulsionist sanitarians, has been passed this session of Parliament with the full knowledge and the silent acquiescence of this Committee, and in defiance of the repeated mandate of the Association at large that all such invasions of professional rights and interests should be resisted. And it is no wonder that this should be so, for the Chairman of the Parliamentary Bills Committee (who is, we believe, the whole Committee in himself) was, next to Mr. Hastings, who inserted these clauses in the York Bill, the chief agent in the promotion of compulsion. Thus it appears that, when the members of the Association issued their orders that compulsory notification should be resisted, those orders went into the hands of a straw committee, and from them into the control of Mr. Hastings' partner in compulsion. We need add to this narrative no further comment than that afforded by the Editor of the *British Medical Journal* himself, who says: "We make no comment upon these facts, beyond the somewhat obvious remark that they show in very startling colours the methods in which we legislate now-a-days in matters affecting the social condition and public liberties."

### Notes on Current Topics.

#### Mr. Erichsen in Scotland.

It must be with very considerable satisfaction that the profession is a spectator of the unusual number of medical men who are about to engage in the struggle for seats in the House of Commons, for it is a common complaint that medicine is far too inadequately represented in the legislative chamber of the country; and that it is desirable to increase the number of such representatives is felt not only in the profession, but as well among the educated classes of the community. The Universities of Edinburgh and St. Andrews have for long been ably represented in the House of Commons by Sir Lyon Playfair; but it is impossible to avoid the suggestion that so far at least as the profession is concerned, the mistake of the public in assuming that because he was described as "Dr." Playfair he was therefore a medical man has been unfortunate; and we have but too much excuse to regret the influence he was able to exert, in a spirit antagonistic to medical reform, over the fortunes of the last abortive Bill. Edinburgh is largely medical in its sympathies, and it is fit and proper for it to return a medical man to Parliament; and it certainly could not find anyone either more worthy or more admirably suited to deserve its confidence than the chosen Liberal candidate of the combined Universities constituency of Edinburgh and St. Andrews. In this capacity Mr. Erichsen recently delivered an address to the electors, in which he clearly expressed his views; and, in a manner that must be generally approved, he declared that for him Party politics occupied a very minor position as compared with the vastly more important matters of national health, and the advancement of the medical profession in a way

to promote the general welfare of the community. The question of reform in the profession naturally occupied the attention of the orator, and while agreeing with him on points of policy, we must urge upon Mr. Erichsen to be more exact in his illustrations. In order to show the disproportion between the representation of medical bodies on the General Council, that is as between Scotch and English Universities, he instanced Durham as being a very small school, and as having an insignificant number of graduates. Now in respect to the number of its graduates actually and yearly, Durham will certainly compare very favourably with Oxford or St. Andrews; and its importance as a teaching centre has certainly much to be said in its favour. We do not, however, in any way dissent from the conclusion drawn as to the need for re-adjusting representation on the Medical Council; but the way in which the need has been enforced in this particular instance was surely a little unfortunate. Mr. Erichsen very properly insists that the status of the profession suffers from inadequate representation, inasmuch as it cannot exercise sufficiently direct influence upon legislation, owing to the paucity of its members in the House. This is an undoubted fact, as also it is that the public suffers through the same cause, owing to the crude manner in which great measures of sanitary reform are discussed by a body of men unlearned by the presence within it of experts in the ways and means of hygiene. We sincerely trust that Mr. Erichsen will be the chosen representative of the constituency he is courting, in the next Parliament, and that he will meet at Westminster a goodly number of his professional brethren who, like himself, shall be entrusted with the duty of legislating for the British public.

#### Suicide of Dr. O'Connor.

A PAINFUL feeling of regret has been aroused by the death, through suicide, of Dr. Maurice O'Connor, senior resident medical officer at St. George's-in-the-East Infirmary. It will be remembered that certain charges have been brought against officers of this institution, and that an inquiry into the circumstances was ordered by the Local Government Board. The investigation was opened on Monday, the 3rd inst., before Mr. Woodhouse, and was in progress when Dr. O'Connor committed the rash act which led to his death, and to which it is assumed he was driven by the mental strain under which he had for some time been suffering, owing to the unfortunate occurrences alluded to. Dr. O'Connor was about to be examined, as he thought, by Mr. Bealey, in relation to the allegations brought against the Matron of the Infirmary, and he was seen to be much agitated when the examining counsel declared that he had no questions to ask Dr. O'Connor. The latter at once left the room, and, proceeding to his own bedchamber, he swallowed no less than twelve grains of strychnia. Medical aid was forthcoming immediately, and every effort made to counteract the influence of the poison, but in vain, and the result was as stated above. An inquest was held the following day by Sir John Humphreys, when a verdict of suicide while temporarily insane was returned. The deceased was sixty-two years

old, and leaves an invalid wife to mourn his loss. On the sad event becoming known the official inquiry was immediately suspended.

### The Royal Free Hospital.

THE annual report of the Royal Free Hospital for the year 1884 has just been published, and presents a very favourable account of the position of the charity. The total receipts for the twelve months reached £16,206 7s. 11d., while the expenditure, including repayment of a loan of £1,000 from the Bankers, was £12,590 4s. 9d., thus leaving a full balance of more than £3,600. Of this amount £1,450 has been invested, and a balance in hand left of £2,165 9s. 8d. The patients relieved in the year numbered 22,758, 1,940 of them being in-patients. There died in the hospital 153; discharges, cured or relieved, reached 1,643, and there were in hospital on December, 31st, 1884, 137 persons under treatment.

### A New Cure for Cancer.

ANOTHER addition to the long list of so-called "Cancer Cures" is chronicled by the *New York Medical Record*, the fresh claimant being a plant called alveloz, the habitat of which is Brazil. The active part of the shrub is the juice, which has a strong cauterising effect, and which is brushed over the surface of the cancerous sore with a camel-hair pencil. Twenty-four hours after the application lint dipped in arnica and water is to be spread on the cancer, and subsequently a fresh application of the alveloz juice made. Inflammation is set up by the remedy, and cicatrisation is ultimately obtained, the good result being vouched for in many cases by Mr. S. S. Schindler, who has written an account of many hitherto unknown Brazilian plants. The same authority asserts that among these are no less than three hundred and twelve which possess high medicinal value, and of which the materia medica is as yet not cognisant, and many of them are said to possess the most remarkable properties. It might be worth while to send out some one from here to report on this superfluity of remedial products, with a view to discovering how far the enthusiasm of Mr. Schindler has led him astray, and to what extent the natural wonders he describes have a real existence in fact.

### Medical versus Legal Coroners.

WE observe that Dr. Cahalan, of Nenagh, is opposed for the coronership of North Tipperary by a solicitor. There is an universal consensus of opinion that this place should be held by a medical man. In such a situation circumstances must from time to time arise with which we think a layman must be unable to deal. We consider that only a medical man can possess that knowledge of the causes of death which would enable the coroner to vindicate the rights of the public in cases of foul play. And our opinion in this case is borne out by the report of the Select Committee of the House of Commons on the qualification required for the post. We wish Dr. Cahalan all success.

### The late Dr. Graham, of Liverpool.

THE sad and untimely death of Dr. A. F. Graham, of Liverpool, has left his young family of four children without any provision for their maintenance and advancement in life. A committee has been formed with a view of raising a fund to place them, as far as possible, in a position to maintain themselves. Dr. Graham was so much respected and so highly esteemed by all who knew him that the committee hope to receive a very generous response to their appeal. The subscription list is headed by a subscription of £100 from the Liverpool Reversionary Society, and one of £21 from Dr. Barr, and it represents a considerable sum, but a large sum of money is still required to enable the committee to carry out the objects which they have in view. Dr. James Barr, M.D., 1 St. Domingo Grove, Liverpool, will afford all required information.

### The Apothecaries' Hall of Ireland.

AT the annual meeting of the Governor and Council, convened by the statute of incorporation, on the 1st inst., the following members were duly elected as office-bearers for the ensuing year:—Governor: Robert Montgomery. Deputy-Governor: Edward J. O'Neill. Court of Directors and Examiners: E. W. Bolland, Thomas Collins, John Evans, A. Harvey, Charles Holmes, Charles H. Leet, Charles Moore, H. P. Nolan, Richard S. O'Flaherty, Sir G. B. Owens, John Ryan, James Shaw, George Wyse. Representative on the General Medical Council: Thomas Collins. The revision of the preliminary and professional curriculum, in accordance with the recent "recommendations" of the General Medical Council was submitted to the meeting, and, being approved of, was ordered to be printed.

### The International Pharmaceutical Congress.

THE President and Council of the British Pharmaceutical Conference have appointed Dr. F. J. B. Quinlan, Fellow and Censor of the King and Queen's College of Physicians in Ireland, and Professor of Materia Medica in the Catholic University, as delegate to represent them at the International Pharmaceutical Congress which will be held in Brussels at the end of this month.

### Removing Microbes from Water.

PROFESSOR FRANKLAND has recently made a series of experiments on the relative efficiency of filtration, agitation with solid particles, and precipitation as a means of removing micro-organisms from water. His method was to determine the number of organisms present in a given volume of the water, before and after filtration. The filtering materials were greensand, silver sand, powdered glass, brickdust, coke, animal charcoal, and spongy iron. These materials were all used in the same state of division, being made to pass through a sieve of forty meshes to the inch. Columns 6 inches in height were used. It was found that only greensand, coke, animal charcoal, and spongy iron wholly removed the micro-organisms from the water filtered through them, and that this power was lost in every case, after the filters had been in operation a month. With the exception of the animal charcoal, however, all these substances, even after being in opera-

tion for a month, continued to remove a very considerable proportion of the organisms present in the unfiltered water; and in this respect coke and spongy iron occupied the first place. Water containing micro-organisms was also agitated with various substances in the same state of division as above mentioned, and after subsidence of the suspended particles, the number of organisms remaining was determined. A gramme of substance was in general agitated with 50 c.c. of water for a period of about fifteen minutes. It was found that a great reduction in the number of organisms could be produced in this way; and the complete removal of all organisms by agitation with coke is especially to be remarked. Precipitation by "Clark's process" also showed that it affords a means of greatly reducing the number of these organisms in water. Dr. Frankland concludes from his experiments that although the production in large quantities of sterilised potable water is a matter of great difficulty, involving the continual renewal of filtering materials, there are numerous and simple methods of treatment which secure a large reduction in the number of organisms present in water.

#### Heat as an Oxytocic.

DR. W. B. ARBERRY writes, in the *New York Medical Record*, on the employment of heat as a means of stimulating the contractions of the womb in cases of labour which do not proceed with satisfactory rapidity. He reports four cases in which this practice proved successful, convulsions having complicated matters in three instances. In all slight teasing pains had continued for some hours, and no progress resulted from them, the patients being thereby much worried and disheartened. His plan is to apply hot "mush" poultices, as hot as can be borne, over the fundus of the womb, and maintain them in succession until labour is completed. In each of the cases quoted the result proved most satisfactory, and in one after large quantities of ergot had been administered without producing the desired effect. It is quite possible that this kind of uterine stimulation might be of service in cases of inertia where no obstacle to delivery exists, and it seems at least worthy of being tried more extensively as a means of putting a limit to protracted labours.

OXIDE of zinc, according to Professor Peterson, of Kiel, is just as good as iodoform in the treatment of wounds, is not poisonous, is cheaper, and does not smell offensively.

PASTEUR'S method of vaccination for cattle-plague has proved completely successful in India for elephants, horses, asses, cows, buffaloes, and sheep.

DR. GOODHART has been selected to deliver the Bradshawe Lecture at the Royal College of Physicians of London on Tuesday next, August 18th. The subject chosen is "Morbid Arterial Tension." All practitioners are admitted on presentation of their card.

IN recognition of the eminent services rendered to the Royal College of Surgeons by Sir Jas. Paget, Bart., it has been decided by the Council to request that gentleman

to sit for a marble bust, to be executed at the expense of the College and placed in some suitable position in the College buildings.

NASAL polypi, it is said, can be readily cured by the injection of a solution of a scruple of tannic acid in a fluid drachm of water. Ten to twenty minims of the solution are to be injected into the polypus. The polypus shrivels, dries up, and comes away without pain or trouble.

WE understand that it has been decided to withhold from publication the Report of Drs. Klein and Gibbes upon Koch's discoveries in relation to the germ theory of cholera, until the conclusions of a Committee appointed by the Secretary of State for India with reference to that Report are also ready.

IN view of the possible approach of cholera to Great Britain, precautions are being taken in accordance with the Government inspectors' advice at all the sea towns round the coast. The port of London is zealously watched, and as much as £4,000 is being spent weekly in deodorising the Thames at the sewage outfalls.

WE desire to state that the report contained in the *British Medical Journal* of the proceedings of the Association in reference to Dr. Jacob's motion in favour of the active organisation of the political influence of the Association at the coming general election is absolutely untrue and garbled, and would, if believed accurate create a false impression. The statement that "members had been called on to make up the requisite number to make a meeting to hear the speaker propose his motion" is, we are authorised by Dr. Jacob to say, totally false. Moreover, the *British Medical Journal* has suppressed the fact that the members who left the room in order to reduce the number present below the necessary quorum were exclusively the members of the Council, and that they were led away by the Editor of the *Journal*, who himself moved the count out. The fact is also suppressed that the meeting was so completely unanimous in favour of Dr. Jacob's resolution that the President stated from the chair that those who were about to support it need not speak. The fact that the *British Medical Journal* has been guilty of deliberate misrepresentation is hardly worthy of notice, but that the gentlemen who form the Council of the Association should allow themselves to participate in such tricks to carry out the policy of the Editor is not calculated to encourage any hope that, in other more weighty matters, they will be less easily led by the nose.

### Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE CRIMINAL LAW AMENDMENT BILL.—What is termed an indignation meeting of men was held on the 4th inst. in the Free Assembly Hall, Edinburgh. There was a crowded attendance, and several prominent citizens of Edinburgh attended. The Lord Provost, it appears, had refused to call a public meeting of the citizens to discuss

this question, and his having done so gave offence to this meeting. Professor Calderwood presided, and having explained that they were met to give expression to their grief at the disclosures contained in the *Pall Mall Gazette*, expressed his opinion that the Criminal Law Amendment Bill was passing the House of Commons now as it could not have passed, but for the horrible disclosures of that paper. They were met with ample evidence of the depth of feeling which had been stirred by these occurrences. The demand for petitions amongst the women in the city had been so very large that it could not be met, and already the women of Edinburgh had sent 3,000 signatures to the House of Commons with reference to the subject. He himself had been waited upon, in connection with this matter, by a representation of the students of the University and by the medical men of the city, while a committee of the working-men of the city had been formed; and the ministers and members of the legal profession had prepared a petition to the Lord Provost asking him to call a public meeting. All round they had evidence that feeling was rising, and he hoped the result would be such practical measures as would not merely help Parliament in carrying the Criminal Law Amendment Bill, but to secure some permanent Vigilance Committee, who would do something strong and hearty. Rev. George Wilson moved—"That this meeting regards with deep grief the disclosures of low morality, base deception, and heartless cruelty made public by the *Pall Mall Gazette*, and generally endorsed by the Committee of Investigation, and recognises in these enormities, which there is reason for fearing are perpetrated to some extent in all our large cities, a solemn call for national humiliation before God, and for an earnest effort by all Christians to elevate the moral and religious life of the country, specially seeking the spiritual good of those separated from social and religious advantages, and those of all ranks of society openly despising justice and righteousness." Mr. James Thom seconded the motion, which was unanimously adopted. Rev. Dr. Whyte moved—"That this meeting, desiring the legal protection of young girls, approves of the provisions of the Criminal Law Amendment Bill, which places in the list of crimes seduction of young girls, procuring for prostitution, and keeping houses or places of business where prostitution is allowed; this meeting further expresses approval of imprisonment for fine as punishment for this, and earnestly desires that clause 9 of the Bill against solicitation on the streets be retained as essential for protection." Dr. Whyte expressed his regret that the press had been so silent on this question, and had not led public opinion as it did on most great questions. The motion having been seconded by Rev. Mr. Meredith, and supported by Mr. A. Telfer, was adopted. On the motion of the Rev. Dr. MacGregor, seconded by the Rev. G. S. Woodrow, it was also resolved to petition in favour of the Criminal Law Amendment Bill, and requesting that the age of girls should be raised from 16 to 18 for protection.

**RIDICULOUS ERROR IN DIAGNOSIS BY A MEDICAL STUDENT.**—Some days ago, in the parish of Inchinan, near Paisley, a body was found in the river Cash near the "water-tub," as the Paisley people, with accurate nautical phraseology, term this locality. The body having been examined by a medical student, was declared to be that of a woman. The circumstance was notified to the registrar of births and deaths, and the body was interred at the expense of the parish in the parish churchyard at Inchinan. The local police-constable, on being made aware of the matter, reported it to the Procurator-Fiscal for the county, who at

once ordered the body to be exhumed in order that identity and cause of death might be ascertained. This was done on Monday, the 3rd inst. The shell was opened, and the doctor, who had been sent from Paisley to examine the remains, found, instead of the body of a woman, that of a dog, which had been in the water so long that it had become hairless and considerably out of shape. The dog was quickly interred, but at a respectable distance from the churchyard!

**MORTALITY IN GLASGOW.**—The low death-rate of 21 per 1,000 has to be recorded for Glasgow for the week ending with Saturday, the 1st inst., as compared with 24 in the previous week, and 24, 25, and 24 in the corresponding periods of 1884, 1883, and 1882 respectively.

**EDINBURGH UNIVERSITY.—GRADUATION CEREMONIAL.**—The graduation ceremonial which usually follows the summer session, and which is primarily set apart for the "capping" of graduates, took place on Saturday, the 1st inst., within the United Presbyterian Synod Hall, Edinburgh. The galleries and the area below them were, as usual, crowded with the friends of the graduates, while the central area was occupied by those about to receive degrees.

**THE HEALTH OF EDINBURGH.**—The report of the medical officer of health relating to the month of July was on the 4th inst., presented to a meeting of the Public Health Committee of Edinburgh Town Council. The number of deaths during July was 293, giving a death-rate of 13.98 per thousand of the estimated population, as compared with a death-rate of over 17 per 1,000 for the corresponding month of last year, and of the five preceding years. Of the deaths 103 were registered as under five years of age, 128 as between five years and sixty years, and 61 as above sixty years. The deaths from disease of the chest numbered 85, or 29 per cent., while 35 deaths, or 11.98 per cent., were due to debility and old age. Diseases of a zymotic nature proved fatal in 16 cases, or 5.47 per cent. of the total mortality. During the month there were 331 cases of infectious diseases reported in terms of section 208 of the Municipal and Police Act, 1879. These comprise 38 of typhoid fever, 6 of diphtheria, 89 of scarlet fever, and 198 of measles. The births registered during the month numbered 575, or 27.3 per cent. of the estimated population, of which 291 were males and 284 females. There were 45 illegitimate births.

For the week ending with Saturday, the 1st inst., the mortality in Edinburgh was 67, and the death-rate only 14 per 1,000. Diseases of the chest accounted for at least 20 deaths, and zymotic causes for 3, of which 2 were due to fever, and 1 to scarlatina. The intimations for the week comprised—Fever 5, diphtheria 3, scarlatina 28, and measles 50.

### Correspondence.

#### SUSCEPTIBILITY TO STRYCHNINE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The following very vivid description of the results of a full dose of liquor strychnia may be interesting to your readers. The drug was in a mixture kept ready for use, and was given in the same dose to three other patients on the same day. The remarkable effects here detailed are evidently due to some idiosyncrasy in the patient. I may add that I subsequently found he had had chorea three times, and that he was at the time in a low, depressed, nervous condition. The following was written to me at my request.

Yours, very truly,

M.D.

London.

"About ten minutes after I had taken one dose of mixture, while writing, I felt I was unable to turn round to

speak to a customer who was behind me, and I answered him without looking at him. This was my first peculiar symptom, and he referred to it as strange on seeing me the next time. About three minutes afterwards I felt I wanted air, and called to the lads to open the door at the end of the shop (outer door), this was hardly done when I felt a swimming sensation through the head, faint, peculiar in the eyes, misty, all in a minute. I called for assistance, endeavoured to get to the door, a lad on each side of me, then came a rush all over me, a sort of shattering to pieces of all my lower regions, was drawn off my legs, but being supported by a strong fellow on one side, was got to the door; this passed while being assisted about twenty feet. Arriving at the door I stood there feeling faint, and this not passing off with the air I was compelled to sit down, then these feelings of being shattered to pieces returned, with pain and not similar to the first, but a more dragging sensation, drawing me up, and as I sat compelling me to turn my feet to the left and my head towards them, drawing my hand (right only, my left holding the seat of chair firmly) into a fist, and curling my fist to my wrist and towards my chin. I fancy I fixed my right arm through the back of the chair, as my back seemed to be drawn so painfully, hence my arm and hand being up, going to my chin, I should say. I was forming nearly a semicircle, prevented doing so entirely by the back of the chair. This passing over I was given some brandy and water, but I could not hold the glass to my mouth; directly I moved my mouth to drink from the glass my right hand was curved round and drawn up to the wrist again, my chin felt peculiar and stiff. If I tried to move, to stand up, or shifted one of my legs I had these terrible shattering feelings making me Oh-o-o-o! and try to pull myself together. I could only speak as if I were paralysed in the throat in that peculiar weak manner, all of one tone, and was bound to close my eyes to speak. For some half hour I was like this, and afraid to attempt to stand or move, but at last I did so, and having raised myself on my legs, could not get my body up from the waist, but on standing up at last, could get along with assistance, but lost all power of supporting myself down a step. With the greatest difficulty I was pulled into a carriage, not being able to raise myself on to the step. All my nerves were at work. If I raised my leg from the ground, sitting down, it was drawn gradually. I felt as if there were a cord down the calf of the left leg—left leg only—drawn up. About two hours after I had taken the mixture I found the same difficulty in taking anything; directly I put a spoon to my mouth and lowered my chin, I felt a fixed sensation which made me nervous, and I gave up the beef-tea I was endeavouring to swallow. In taking off my boots, if my legs were stretched out and the boot pulled I had the electric shock right through it, but if I curled my leg *inwards* and pulled my boot off myself in the usual manner I felt nothing that I recollect. For some three or four days I suffered from restlessness at night, no circulation in my body (at night only), insecurity on my feet, great difficulty in supporting myself on the one foot in coming down stairs. On returning to my work in about five days, for about a week I was driven on, so to say, in speech and writing, particularly the latter. It seemed impossible to help making mistakes in this way. I addressed a letter Mrs. Ashton instead of Mrs. Salmon, Ashton Keynes, Mrs. Usk instead of Mrs. Gastard, Usk, and in many instances wrote the following word instead of the one I should have written. Great nervousness also annoyed me very much—banging of a door, or if a dog ran out of a gate startled me. I imagined Hansom cabs running away during my walk to and from business.

I may mention that the only time I lost consciousness was for the few seconds I was being assisted to the door for air, when the first shattering of my nerves took place, while a doctor called in was taking my temperature under my tongue.—he was telling me "now don't bite it," and in trying to hold myself very still, *and not bite the top of his pencil case off with chloroform in as I thought*, this seemed to calm me. I had something to think about, and this tended to control my nerves, at least I thought so, it was after this I was removed, and it convinces me how important it is that anything happening to upset the nervous system, should be counterbalanced by something to calm them. Had either of the two medical men I called in, given me something, if only cold water, assuring me I should have relief in a minute, and not told me what it was, I should have recovered more quickly, it would have given me confidence in myself, whereas

I had none and thus became more nervous and more frightened, and my great anxiety was to find the someone who would give me the one thing, I felt necessary to set me right. Of course I had great palpitation of the heart, and I felt that might settle me.

I have written as clear an account as I am able of my unfortunate affair, and hope it may be useful to you.

Yours truly,  
M.

## Literature.

### SURGICAL DELUSIONS AND FOLLIES. (a)

THIS little book, which can easily be read through in an hour, is stated on the title-page to be a revision of the Address in Surgery for 1884 of the Medical Society of the State of Pennsylvania.

As may be expected from its title, it contains many trite remarks and blows at time-honoured customs. Though replete with truisms and sound surgical doctrine, there is not much, if any, original matter to be found in it. Under the first half of the book devoted to surgical delusions, the opinion that chloroform is a safe anæsthetic is strongly combated; a mixture of chloroform and ether is also considered objectionable, as it still contains the dangerous ingredient. In this opinion we cordially concur. The author speaks strongly (as Mr. Hutchinson and others have done in England) of the so-called symptoms of compression not being due to displacing pressure exerted on the brain substance, and recommends the orthodox treatment of making an exploratory incision in all subcutaneous injuries of the head. We can hardly agree with him "that all depressed fractures with possible existence of splintering are to be immediately trephined" with utter disregard of the absence of all symptoms and the presence of the venous sinuses. If the splintering were *probable* trephining is laid down as a rule in all our text-books. Early removal of tumours, short confinement of fractures in splints, are surely universally adopted, but whether the following treatment for strangulated hernia is practical is a matter of opinion: "Taxis under ether, a half day's treatment with cold applications and morphia internally, and then a second moderate attempt at taxis, followed if unsuccessful by immediate operation." If a case be severe enough to be put under an anæsthetic not many surgeons would allow the patient to come round again with the hernia unreduced. Amongst other things, we are told that all styptics are useless, and that the practice of padding with cotton and tying up eyes that have been subjected to cataract operations is foolish, and needs loud-voiced condemnation.

Dr. Roberts likes ether administered on a napkin covered by a towel, and stigmatises all inhalers as possible vehicles of syphilitic saliva. In case the trachea becomes full of mucus during an operation the patient is to be turned over on the abdomen with the head dependent, but directions are not given if abdominal section is being performed. The subject of damage done to healthy tissues by tourniquets or elastic bandages placed on a limb while awaiting reaction prior to amputation is ably handled. It is insisted upon that the bandage should be firmly applied *upon or just above* the damaged tissues. We are told that rusty iron wire for sutures is not objectionable, that clean towels obtained at a patient's house are sure to be aseptic, and that lead and opium lotion for contusions is useless. That the aspirator is of more use as a means of diagnosis than as a means of treatment is very true, as collections of pus are often repeatedly aspirated when a free incision is indicated. Altogether this little book is interesting, and is sure to afford considerable instruction.

### ELIJAH THE PROPHET OF FIRE. (b)

DR. BIGGER has found time amid the engrossing cares of practice to woo the epic muse; and his present effort, although not so ambitious as the "Collegians," is a creditable

(a) "Surgical Delusions and Follies." By John B. Roberts, A.M., M.D., Professor of Anatomy and Surgery in the Philadelphia Poly-clinic, Philadelphia: P. Blakiston, Son, & Co. 1884.  
(b) "Elijah the Prophet of Fire." By S. Lenox Bigger, M.D. F.R.C.S. Dublin: Hodges & Figgis. 8vo. Pp. 140.

piece of sacred poetry. It is admirably got up and printed, and is illustrated by a number of fine etchings. These are full of taste and genius. We would particularise Hagar and Ishmael at p. 34; and still more the follower of Elijah on the watch on the crest of Mount Carmel, at p. 62; this latter is very fine. These etchings are understood to be the work of a young lady artist.

**Obituary.**

**PATRICK WILLIAM EARL, OF DUBLIN.**

ONE of the few surviving analytical chemists of the old school has just passed away from our midst in the person of Patrick William Earl, whose decease took place on Tuesday, the 4th inst., at his residence, 40 Westland Row. Mr. Earl came of an old Irish family, the Errills (Anglicised Earl), of Carbury, co. Kildare, where a near relative of his, the Rev. Edward Errill, was parish priest in the time of the celebrated Bishop Doyle. At an early age the deceased became the pupil of the late eminent Dr. John Aldridge, Professor of Chemistry in the Cecilia Street School of Medicine, and succeeded Dr. Aldridge in the management of a large manufacturing laboratory attached to the establishment of Messrs. Bewley and Evans in this city, in which laboratory he spent his health, strength, and talents for a period of forty years, till the firm was about being merged into a limited liability company seven years ago. Mr. Earl, at that time broken down in health by his long exertions and the deleterious nature of his avocations, received a shock which laid him on a bed of suffering from which he never rose, in the reception of a notice dispensing with his further services, on the ground of the pending alterations in the firm, and giving him no compensation for the faithful services of a lifetime. The deceased was well known as a talented member of his profession, though a natural diffidence which he possessed prevented his name coming much under public notice. In view of the Royal Commission now sitting on the industrial resources of Ireland, it may be of interest to state that Mr. Earl took an active part at one time in an undertaking set on foot by Lord George Hill, Sir James Dombraim, Dr. Aldridge, and others, for the purpose of obtaining iodine and the various valuable salts found in seaweed by a process known as McArdle's.

Amongst the many chemists who graduated under the deceased, and who now occupy high positions throughout the United Kingdom and America, may be mentioned the name of our present City Analyst, Sir Charles Cameron, M.D., President of the Royal College of Surgeons.

We understand that his widow, who, up to the present, with her invalid husband, has been entirely dependent on the exertions of their children, will shortly bring out one of the many valuable medical preparations invented by the late Mr. Earl, for the benefit of herself and family.

**Medical News.**

**The Medico-Psychological Association.**—The annual general meeting of this Association was held at Queen's College, Cork, on the 4th August, under the presidency of Dr. J. A. Eames. After a vote of thanks to Dr. Rayner, the retiring President, Dr. Savage, of Bethlem Hospital, was elected President for the next year. The Association considered and approved of a scheme for the granting of certificates in Psychological Medicine, and a paper was read by Dr. Hack Tuke on a case of Moral Insanity. At the adjournment for luncheon a visit was paid to the Cork District Lunatic Asylum, which contains nearly one thousand patients, and which includes, among other well-ordered arrangements, a very complete system of Turkish baths. At the afternoon sitting an address was delivered by Dr. Eames, and the members of the Association afterwards dined together at Queenstown, which rising place, it was stated, had never before been chosen for a scientific association's meeting. On the following days excursions were made to Killarney and other places.

**University of London.**—The following is a list of candidates who passed the recent Intermediate Examinations in Medicine (entire Examination):—

*First Division.*—John H. Abram, Evelyn O. Ashe, Percy Ashworth

B.Sc., Marnaduke Bannister, George Black, Ernest H. Brock, Robert J. Carter, Walter S. Calman, Samuel Cuff, Henry P. Dean, B.Sc., Edward Deanealy, Horace Duncan, Frank Fawcett, Theodore Fisher, George T. Gifford, Thomas C. Gilchrist, Cyril W. Jecks, Harold Johnson, Alfredo A. Kanthack, B.A., George H. Lang, Milton P. Ledward, William J. Maillard, Hyde Marriott, B.Sc., William P. May, B.Sc., Brian Melland, Alfred A. Mumford, George H. O'Reilly, Ernest B. Randall, George E. Rennie, B.A., Sydney John L. Roberts, B.A., B.Sc., Harold K. Roper, Ernest A. Sadler, Harry A. Sansom, Ramon A. Sawyer, Arnold Scott, William A. Slater, B.Sc., Guy B. Smith, Reginald V. Solly, Ernest H. Starling, William P. Stocks, Henry Symonds, Frederick H. Taylor, Alfred H. Tubby, John O. Tunstall, John Wilkie, William G. Williams.

*Second Division.*—Arthur Baxendell, James T. Bayes, Lewis T. F. Bryett, Solomon Bueno de Mesquita, James J. Buist, Cyril C. Barrow Burt, John T. Calvert, Henry E. L. Canney, Herbert A. W. Coryn, Rainsford F. Gill, Wilfred T. Grenfell, Nathan C. Haring, Edwin B. Hastings, Arthur E. Hensley, Henry T. Kelsall, Isabella M. Macdonald, Ludovic W. D. Mair, Enoch Moss, Henry A. L. Pope, Philip N. Randall, John J. Redfern, Bernard Relton, Joseph C. Rosell, Charles F. Routh, Frank P. Sarjant, Ernest H. Snell, Theodore M. Stiles, Stuart A. Tidey, Herbert E. Vincent, Howard P. Ward, Helen Webb, John P. Williams, Marcus G. Yunge-Bateman.

*Including Physiology.—First Division.*—Charles F. M. Althorp, Arthur E. Glee, John E. Gould, Francis Harris, Berkeley G. A. Moynihan, John A. Shaw, Christopher P. Spink, Frank A. Spreat, William E. Tresidder, Joseph W. Winterburne.

*Second Division.*—Frederic W. Abbott, George Barlow, Richard O. Bowman, Arthur T. Brown.

*Physiology only.—Second Division.*—William H. Kelson, Charles P. Oliver, William N. Bardon, Arthur H. L. Stewart.

**University of Glasgow.**—The following degrees have been conferred during the Summer Session, 1885:—

*Doctor of Medicine.*

| Rawes, William Maer         | White, Frank Faulder, L.R.C.P. |

The following were admitted on August 4th:—

Anderson, Adam Rivers Steele  
Andrews, Edward Collingwood  
Beale, Thomas Miles  
Burd, Edward Lycott  
Child, Letterstedt Frederick  
Dreaper, William Grey  
Hart, George,  
Martin, Francis G. Clifton, L.S.A.  
Matthias, Hugh, Brodric  
Mourliyan, Edward Pain  
Nicholls, Hubert

The following were admitted on August 5th:—

Chapple, A. D., L.R.C.P. Lond.  
Dagg, Trevor Augustus, L.S.A.  
Lavis, Harry Brandrett, L.S.A.  
Lermitte, Charles Gower, L.S.A.  
Lloyd, Percival A., L.R.C.P.  
Lond.

Royal College of Surgeons in Ireland.—The following candidates have been admitted Fellows of the College after examinations:—

Broomfield, Humphrey | White, George B.

O'Connor, William Patrick  
Parker, Joseph Edmund  
Shadbolt, Lionel Pierpont  
Sharland, Arthur  
Smart, William Herbert  
Sutton, Alfred Martin  
Travis, George Lewis  
Upham, Charles Hazlett  
Watson, William Jones  
Whittaker, Joseph  
Williams, Herbert Leader

Lynch, George Wm. A., L.R.C.P.  
Lond.  
Raghib, Edmund, L.S.A.  
Reed, Henry A., L.R.C.P. Lond.  
Wilson, Albert, L.R.C.P. Lond.

## Notices to Correspondents.

A FELLOW (Edinburgh).—As anticipated in our last issue, it has now been finally decided to abandon the Bill for the present session.

MARYLEBONE.—We do not care to express an opinion while the case is *sub judice*.

MIDLANDS.—It is hardly a question we should care to answer, not knowing the full circumstances of the case. We would rather counsel you to consult one of the recognised medical agents, who would be in a better position to advise the best course to pursue.

MR. F. E. R. (Manchester).—It is so manifestly a puff that it will carry its own condemnation. We prefer not to give it the additional publicity of our columns, and would advise you also to take no notice of it.

DEAN.—Our Students' number will be published on September 23rd. We shall be glad to receive the particulars.

COTTAGE HOSPITAL.—1. Donville's "Manual for Hospital Nurses and others Attending the Sick." 2. Naphey's "Modern Medical Therapeutics," or Ringer's "Therapeutics." 3. Fothergill's "Diet for Invalids."

A COMPLAINING AUTHOR has not enclosed his card in evidence of good faith.

DR. STORMONT.—The use of a back splint is advocated by many practical surgeons. We have, however, seen equally good results without it; and, unless really deemed necessary, we should advise its omission.

MR. GETTING.—The name is not one commonly met with in this country, and we are not acquainted with the surgeon in question. We have made the inquiry you request, but without result.

MR. PARTINGTON.—You had better consult a specialist, and adhere strictly to the instructions he gives.

MR. J. L. WELDON.—Strict attention to cleanliness and a careful abstinence from stimulants on the part of the patient will do more than medication in such a case. Tonic remedies would also be productive of good.

DR. JARREWAY will please accept our thanks for his communication.

DR. CAMPION.—The present edition of Holmes' Surgery is in three volumes only; the preceding (second) edition was published in five volumes. Messrs. Baillière & Co. will supply the work on your order.

A LADY STUDENT.—We must refer you to your teacher, to whom alone such questions should be addressed.

MR. MATTHEW BELL.—The small work entitled "Aids to Medicine," by Dr. Armand Semple, is said to be useful to students under certain circumstances.

DR. JAMESON.—Fractured olecranon very rarely unites, but a good limb, and useful, is as a rule obtained.

MR. ARNOLD.—The subject shall have early attention, and you shall be communicated with on the matter.

### OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY—Hospital for Women, 2 p.m.—Metropolitan Free, 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Orthopaedic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Mark's, 2 p.m.  
TUESDAY—Cancer Hospital, Brompton, 3 p.m.—Guy's 1.30 p.m.—St. Mark's, 9 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Westminster, 2 p.m.—West London, 2 p.m.  
WEDNESDAY—Great Northern, 2 p.m.—London, 2 p.m.—Middlesex, 1 p.m.—National Orthopaedic, 10 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Samaritan Free Hospital for Women and Children, 2.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Mary's, 1.30 p.m.—St. Peter's, 2 p.m.—St. Thomas's, 1.30 p.m.—University College, 2 p.m.  
THURSDAY—Central London Ophthalmic, 1 p.m.—Charing Cross, 2 p.m.—Hospital for Diseases of the Throat, 2 p.m.—Hospital for Women, 2 p.m.—London, 2 p.m.—North-west London,

2.30 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. George's, 1 p.m.  
FRIDAY—Central London Ophthalmic, 2 p.m.—East London Hospital for Children, 2 p.m.—Guy's, 1.30 p.m.—King's College, 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal South London Ophthalmic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Thomas's (Ophthalmic Department), 2 p.m.  
SATURDAY—King's College, 1 p.m.—London, 2 p.m.—Royal Free 9 a.m. and 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 1.30 p.m.

## Vacancies.

Brighton.—Sussex County Hospital.—Honorary Assistant Physician. Applications, with testimonials, to the Secretary, before September 2.  
Brompton.—Hospital for Consumption.—Resident Clinical Assistant Board, but no salary provided. Applications by August 15. (See advt.)  
Chatham.—St. Bartholomew's Hospital.—Assistant House Surgeon. Salary, £100, with board, &c. Endorsed applications to the House Committee by September 30.  
Lincoln County Hospital.—House Surgeon. Salary, £100 per annum, with board, lodging, &c. Applications, with testimonials, to the Secretary, on or before August 15.  
Mason Science College, Birmingham.—Demonstrator in Physiological Department. Applications on or before August 26.  
Reading.—Royal Berks Hospital.—House Surgeon. Salary, £90 per annum, with board and lodging. Applications, with testimonials, to the Secretary by August 15.  
Salisbury Infirmary.—House Surgeon. Salary, £100, with board. Applications to the Secretary by August 21.  
Stockton-upon-Tees Hospital.—House Surgeon (non-resident). Salary, £200 per annum. Applications, with testimonials, to the Secretary, not later than August 24.

## Appointments.

DRESCHELD, J., M.D. Wurz, F.R.C.P. Lond., Visiting Physician to the Royal Lunatic Asylum, Manchester.  
FIRMAN, C. G., L.F.P.S. Glas., M.R.C.S., Medical Officer for the Wandford District of the Stamford Union.  
FITZGERALD, W. E., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer for the Hoysthorpe District of the Spilsby Union.  
GILBERTSON, J. H., M.R.C.S., Medical Officer for the Second District of the Hitchin Union.  
HAWKINS, F. H., M.B., Physician to the St. George's and St. James' Dispensary, London.  
HOLLIS, E., M.D. Ed., Medical Officer of Health for the Woodbridge Rural Sanitary District.  
HOWE, J. D., M.R.C.S., L.S.A. Lond., Assistant Medical Officer to Monsal Fever Hospital, Manchester.  
JAMES, P., L.R.C.P. Ed., M.R.C.S., Medical Officer for the Western District of the Bridgend and Cowbridge Union.  
JOHNSON, G. H., L.R.C.P. Ed., M.R.C.S., Honorary Surgeon to the Teignmouth Infirmary.  
LANGDON, H. W., M.R.C.S., L.S.A. Lond., Medical Officer for the Seventh District of the Bath Union.  
MORRIS, E. F., M.R.C.S., House Surgeon to the York County Hospital.  
OWEN, R., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the South Sefton District of the West Derby Union.  
RANDALL, W., L.R.C.P. Ed., M.R.C.S., Medical Officer for the Bridgend District of the Bridgend and Cowbridge Union.  
SIMMONS, F., M.B. Ed., Resident Physician to the Chelsea Hospital for Women.  
SIMPSON, H., M.D. Lond., M.R.C.S., L.S.A. Lond., Visiting Physician to the Royal Lunatic Asylum, Manchester.  
THOMAS, D. J., L.R.C.P. Ed., M.R.C.S., Medical Officer for the Ogmores District of the Bridgend and Cowbridge Union.

## Births.

ADRIEN.—July 30, at Balbriggan, Co. Dublin, the wife of Edward W. Adrien, M.K.Q.C.P.I., M.R.C.S. Eng., of a son.  
BENNETT.—August 10, at Rawal Pindi, India, the wife of Surgeon-Major Bennett, of a son.  
LOVEGROVE.—August 5, at Nottingham, the wife of T. Ernest Lovegrove, M.R.C.S., of a daughter.  
O'CONNOR.—August 1, the wife of Bernard O'Connor, M.D., M.R.C.P., of a son.

## Marriages.

CAHILL.—NORTON.—July 27, at the Pro-Cathedral, Marlborough Street, Dublin, Thomas Emond Cahill, Physician and Surgeon, to Bridget (Bee), only daughter of William Norton, Esq., of Ballingarry.  
GILES.—SEACOMBE.—August 6, at Holy Trinity Church, Shrewsbury, Bernard F. Giles, M.D., of Wem, Salop, to Mary, eldest daughter of the late T. Harrison Seacombe, C.E.

## Deaths.

EARL.—August 4, at his residence, 40 Westland Row, Dublin, after long suffering, Patrick William Earl, Esq.  
FRANKLIN.—August 6, at his residence, Carlisle Terrace, Malahide, William Henry Palmer Franklin, F.R.C.S.I.  
FRENCH.—July 28, at Ballygar, Co. Galway, John Gay French, M.D., F.R.C.S. Lond., Surgeon-Major H.B.M.S., aged 46.  
LIVING.—August 2, at 22 Queen Anne Street, London, W., Frances Jane, the wife of Edward Living, M.D., aged 62.  
MILLIGAN.—July 26, at Hayfield, Thornhill, Dumfriesshire, John Laidlaw Milligan, M.D.  
NICHOLSON.—July 22, at his residence, 53 George Street, Hull, John Lee Nicholson, M.R.C.S., L.S.A. Lond., aged 66.

### THE ATTITUDE OF THE MEDICAL PROFESSION IN REGARD TO THE SIGNING OF CERTIFICATES FOR ASYLUM COMMITMENT, AND TO LUNACY LEGISLATION. (a)

By A. R. TURNBULL, M.B.,

Medical Superintendent of the Fife and Kinross District Asylum.

(Concluded from page 142.)

THE new English Bill is very clear regarding the judicial action of the magistrate. It enacts that he shall, before giving his order, satisfy himself that the evidence adduced by the medical witnesses is sufficient, and that he shall have the power to institute further inquiry if he thinks it necessary. Here arises the question, What is the exact position of the sheriff in the Scotch procedure? The statutes do not define it clearly; and in practice different sheriffs act in different ways. Some consider that if the medical certificates, &c., are drawn in proper form, the sheriff's duty is simply the ministerial one of signing the warrant, and that he is not required to consider the sufficiency or insufficiency of the facts stated as indicating the insanity. Other sheriffs have refused to sign the warrant when they considered the facts stated to be insufficient. In the statutory form of sheriff's order, the wording is the sheriff *having had produced* to him two medical certificates showing that A. B. is insane, grants warrant, &c. There is no mention of considering or reviewing the certificates in any way; and from this it might perhaps be inferred that the sheriff's action is ministerial. On the other hand, the section of the Lunacy Acts (section 14, 25 and 26 Vict., cap. 54), which deals with the sheriff's order enacts that the sheriff *may* give a warrant. It is nowhere stated that he *shall* give a warrant. Here, then, it would appear that he is

not necessarily bound down to act in a purely ministerial capacity; and the inference would be that he can act in a more or less judicial way. If the sheriff's position were simply ministerial, the petitioner and the medical men would have power to compel the granting of the warrant, no matter how weak the evidence of insanity as given in the certificates might be; the sheriff's intervention would be little better than a mere formality, and the safeguard that is got from his judicial action would be lost. As a matter of fact, many of the Scotch sheriffs do act judicially; and it would perhaps be an improvement in the statutes to have it more distinctly brought out that the sheriff's position in the procedure is judicial.

Lord Shaftesbury, while approving of much of the proposed new legislation, objects very strongly to the introduction of the magistrate. He argues that it will add greatly to the expense and publicity, and that the authority given to the magistrate to make further inquiry when he thinks right puts in his hands an enormous power, the exercise of which would often cause a great deal of vexation and suffering to the relatives of patients. He holds that the dread of this publicity and exposure would prove a very serious bar to early treatment, and would result in a vast increase of clandestine confinement, in the detaining in private houses of cases that are really insane under the pretence of their suffering from other forms of nervous disorder, and in many patients being sent abroad for asylum treatment, and thus removed from proper supervision, in preference to being placed in English asylums. The magistrate's order would overrule and set aside certificates signed by perhaps the most eminent medical men in England, and the best men in our profession would thus decline to give certificates, and would leave the work altogether in the hands of the most inferior practitioners. It is mainly to Lord Shaftesbury that we owe the beneficent lunacy legislation of the last fifty-seven years, which has revolutionised the care and treatment of the insane; and any opinion put forward by him must necessarily carry very great weight. But it is permissible to point to the experience of the Scotch system, in which the sheriff takes the position of the magistrate in the new English procedure.

(a) Read at a Meeting of the Fifeshire Medical Association at Dunfermline.

That system has been in operation for twenty-seven years, and has worked smoothly and expeditiously. The presenting of the petition and certificates to the sheriff, and the getting of his order, do not in the least imply any undue publicity or exposure; the expense is very trifling, and in practice it has not been found that the procedure is in any way a hindrance to early treatment, or objected to by the patient's friends, or attended by any of the unfortunate effects which Lord Shaftesbury dreads. If the views urged in this paper are correct, there is no reason why every member of our profession should not be perfectly willing to submit his certificate to the inspection of the magistrate; and surely there need not be any fear that the English magistrate will use his discretionary power in a less reasonable and tolerant way than the Scotch sheriff has done. If arrangements are made by which a magistrate is readily accessible in each district of the country, there should be nothing to prevent the new English procedure from working as smoothly, expeditiously, and satisfactorily as the Scotch procedure has done.

Another point may here be conveniently considered—viz., the separate or conjoint action of the two medical men who certify the lunatic. The present statutory form of certificate, both in England and in Scotland, bears that the doctor has "separately from any other medical practitioner" visited and personally examined the patient. The new Bill proposes to add the following clause to the certificate:—"I am not acquainted with the contents of any other medical certificate relating to the mental condition of the said patient made within the last seven days." It is, of course, evident that the intention of these qualifying clauses is to secure two independent medical opinions that the patient is insane.

It is held by some that the clause "separately from any other medical practitioner" precludes any consultation by the medical men; and Lord Coleridge considered that the two certificates should be written on separate sheets of paper, so that the one doctor's certificate should not be seen by the other doctor. The additional clause in the certificate in the new Bill is still more definite in limiting the possibility of conjoint action by the medical men. It is, however, very doubtful if any good purpose is served by this extreme restriction. In lunacy, as in other diseases, consultation by the medical men is often of the greatest service, and may be called for in the interests of the patient; and the restriction of it may make the lunacy procedure unnecessarily complicated and cumbersome. Take an instance that would occur frequently in actual practice. Suppose the ordinary family physician has an insane patient for whom he considers asylum treatment necessary, and that for the greater satisfaction of the friends he suggests that the opinion of a doctor specially engaged in lunacy work be also got. Naturally the first physician informs the consultant of the history and symptoms of the case, and they confer together regarding the patient and his proper treatment. If asylum treatment is deemed right, both the doctors are by their consultation precluded from giving the certificates; and before the patient can be committed two independent medical men must be called in, both of whom should in strict law be kept in ignorance of the opinion of the first two doctors. This means needless complication and expense, and amounts almost to a *reductio ad absurdum*, and the patient's interests are not made any more secure by it. Consultation by the medical men, therefore, ought not to be prevented. All that the certificate should require should be that each doctor has in a separate visit to the patient been able to observe, independently for himself, facts sufficient to prove the insanity and warrant him in signing the certificate. The present wording of the certificate—"I have, on such a date, at such a place, separately from any other medical practitioner, personally examined the patient"—possibly implies nothing more than this, and in practice many medical men act on the opinion that it does not forbid consultation. If this be correct, the present form

of certificate is satisfactory; but as there is much doubt on the point, it might be well to indicate clearly that separate visitation only is required, and that consultation is not forbidden. By the same reasoning, the additional words in the new Bill are wrong in principle, and should be omitted.

There are minor details in the new Act, limiting the relationship of those who take part in the lunacy procedure. If the Bill becomes law the committal of a private patient to an asylum will require the active concurrence of the following five persons:—(1) the petitioner, (2 and 3) the two medical men who give the certificates, (4) the magistrate who signs the order, and (5) the superintendent of the asylum. These persons must all be independent of each other, and not related; and, further, the patient is under the protection of the Commissioners in Lunacy and the visiting justices. The arrangement therefore gives a very good guarantee that the power of asylum committal cannot easily be exercised in any improper or unnecessary way.

III. *Protection of Medical Men.*—It is a very striking fact that the lawsuits against medical men for signing lunacy certificates have been confined to England, and that in Scotland, since the introduction of the present procedure in 1858, there has not been any instance of an action against a medical man for his certificate. There is no doubt that the immunity thus enjoyed by the Scotch practitioners is mainly due to the general belief that the action of the sheriff covers the action of the medical man, and that consequently it is not competent to sue them in court. Lord Shaftesbury urges as another objection to the introduction of the magistrate that "the patients will be deprived of a right they now possess. The signature of the magistrate would, he believes, in law, and certainly in the estimation of a jury, cover the parties concerned in the certificate, and take from the patient his right of action after liberation for any misconduct on the part of the doctors." That the magistrate's intervention should give a very considerable degree of protection to medical men, and prevent the occurrence of lawsuits such as have been frequent of late, will be to most of us a strong argument for, instead of against, having the magistrate. The experience of the Scotch system would lead us to expect that the action of the magistrate, as provided for in the new Bill, will suffice to get us all the protection that is needed; but if, as some think, this would not necessarily be so, then a special clause should be inserted in the Bill to secure it. The State has called on medical men to act for the care of the insane, and has made their certificates an essential part of the procedure, and it *ought* to give them due protection in the discharge of that duty, just as it protects other persons in their carrying out of legal duties. We have here taken the view that the certificate is simply written expert evidence given for the purpose of setting a certain legal procedure in motion, and as such it ought to be on the same footing as evidence given in a court of law. That is to say, it should be privileged, not actionable, except on the ground that the statements in it are false either from wilfulness or from culpable carelessness in the examination. The inspection by the magistrate should be a guarantee that the certificates are drawn in proper form, and contain sufficient evidence to justify procedure upon them; and medical men are liable to have the certificates returned or refused if they are not satisfactory in these respects. But once passed by the magistrate the certificate ought not to be actionable except on the grounds mentioned above. I would go further, and would, with the view of protecting the medical man from even the risk of prosecution being threatened on insufficient grounds, require that the litigious person should first appear in court, and show reason why the question should be opened up, before being allowed to bring an action directly against the doctor.

Certain enactments in the new Bill bear on the continued detention of patients in asylums, and on private

asylums; but these do not affect the medical profession at large, and therefore, do not fall within the scope of this paper.

The conclusions arrived at may be stated shortly as follows:—

1. The principle of intervention of the magistrate is desirable in the interests both of patients and of medical men, and should be cordially accepted by our profession.

2. The present Scotch system has worked smoothly since its introduction in 1858; it is satisfactory in practice, and conserves the interests of the patients. It would, however, be an improvement to have the judicial position of the sheriff in the procedure more clearly indicated.

3. The present procedure for private patients in England requires considerable amendment. The changes proposed with this view in the new Bill are based on right principles, and will probably secure all that is required.

4. The English procedure for pauper patients is but slightly affected by the new Bill, is unsatisfactory, and ought to be amended by making it similar to the new procedure for private cases.

6. The statutory form of medical certificate should require separate visitation and examination only, and should not forbid consultation by the medical men. The additional words proposed in the new Act are objectionable, and should be omitted.

6. It has been found in practice that efficient protection of medical men is obtained at present under the Scotch system. The amended procedure of the new Bill will probably suffice to secure the same result in England; but this might be more assured by the introduction of a special clause giving suitable protection to those who sign the certificates.

## THE EMERGENCIES OF SURGERY.

*Being a Course of Lectures Delivered in the MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.*

By LAMBERT HEPENSTAL ORMSBY, M.D., F.R.C.S.,

Lecturer on Clinical and Operative Surgery, Surgeon to the Meath Hospital and County Dublin Infirmary; Surgeon to the Children's Hospital, &c.

### LECTURE I.

#### INJURIES OF HEAD AND FACE.

(Continued from page 139.)

*Fracture of the middle cranial fossa*, in this, one would expect to find the fracture extending through the great wing of the sphenoid, the petrous portion of the temporal bone, with injury to the tympanum. This in all probability would be followed by symptoms of compression and bleeding from the ears of a very profuse character, followed by a clear, serous discharge, which wells up in the ear, but does not flow over unless the patient is lying on the affected side, when the pillow is saturated by the continual flow of fluid. It must be remembered, however, that a hasty diagnosis of fracture of the base should not be made if the *only* symptom present was bleeding from the ears, as this hæmorrhage may come from the external auditory canal, the membrana tympani, after slight injury, quite independently of fracture. Again, in some cases you do not have either bleeding from the ears or the flow of the serous or sub-arachnoid fluid, and still there may be fracture of the middle cranial fossa present.

*Fracture of the posterior cranial fossa* is not so easily defined; the fissure generally extends across the occipital bone, ending in the foramen magnum. This may be indicated by great extravasation of blood down the superior and lateral aspect of the neck. However, this appearance is not constant. Symptoms of compression will be generally present as well.

*Prognosis.*—In extensive fracture of the base, my opinion is, that such injuries are always fatal, and because the symptoms at first may not be serious, is no reason to mislead you or throw you off your guard; the patient may live a few days or even longer, but still I believe the result is the same, even if the case appears to be serious at first and symptoms present that usually indicate fracture of the base, and the patient afterwards recovers. I would think the presumptive evidence would favour the belief of the non-existence of a fracture. I do not, however, deny that it is possible for a patient with a very small, linear fissure of the base where the brain tissue or its membranes are not torn, contused, or implicated, to recover under judicious treatment.

*Treatment.*—On hearing the history of the accident, place the patient in bed, examine the entire head carefully; if you are not satisfied, shave the head to examine more thoroughly for extravasation or otherwise. Apply cold to the head; a drop of croton oil may be inserted in a little bit of butter and placed on the back of the tongue. Examine the limbs and side for paralysis, and treat any symptoms that may arise. Examine the bladder, and, if full, draw off water twice a day with a catheter. Place the patient in a dark room, and, if unconscious, watch for the slightest sign of rallying or recovery of perception.

*Hernia Cerebri (Fungus Cerebri).*—Signifies a protrusion of the brain substance after a compound fracture of the skull where the dura mater is torn or lacerated, the immediate result of a severe fall or blow, or where some foreign body has penetrated the brain substance. Or it may occur subsequent to such an injury, where the dura mater may be destroyed by ulceration in a situation where a portion of the skull is removed, allowing the brain to protrude, which it does, having the appearance of a round, nodulated, compressible tumour, increasing in size as it continues: this protrusion is far more liable to occur in cases where there is a small aperture than through a large opening. Two varieties of this condition have been described (Guthrie). *In the first form* which occurs within the first two days after the accident, the small tumour appears to consist in a great measure of coagulated blood, the result of hæmorrhage into the brain substance near the surface, it is attended very early by delirium, and is nearly always fatal, no matter what treatment is adopted. *In the second form*, the tumour is mainly composed of brain substance infiltrated with lymph and extravasated blood, and appears at first covered with dura mater, which, however, soon sloughs, owing to its being constricted by constant pressure at the neck of the tumour, where it protrudes by the small aperture through the skull; it then appears as a greyish-white fungous-looking mass. If by any chance it be removed, it is quickly succeeded by a fresh protrusion of brain and fungous granulation, covered over by a copious discharge of pus. The patient may probably be delirious, indicating phrenitis; this will be sooner or later followed by coma and death, or the patient may sink from exhaustion and irritative fever.

*Treatment.*—It is recommended in some instances to attempt to return the small tumour through the aperture provided it is small and that it has not existed for any time, and that the dura mater remains uninjured. When it is replaced, a small compress is firmly fixed over the aperture so as to prevent a return. This procedure must, however, be carried out with caution, for in cases where bandaging and compression have been adopted, cerebral mischief soon appears, producing stupor, and afterwards profound coma. In the second form mentioned, it is recommended to shave off the fungus mass on a level with the brain, and apply a wet compress of lint and a bandage. There is a great liability for the fungus to grow again after being sliced off. The fungoid granulations which spring from an exposed dura mater have been treated by the application of nitrate of silver to its surface.

*Paracentesis Capitis*, signifies a form of operation that has been recommended for puncturing the dura mater in

the last stages of chronic hydrocephalus in children with a view to relieve urgent symptoms, at best, it is only palliative as the fluid soon collects. To perform the operation a very fine trocar or grooved needle is introduced perpendicular to the surface through the anterior fontanelle; care must be taken to avoid wounding the longitudinal sinus, by keeping well to the side will obviate this. All the fluid should not be withdrawn at once. From two to three ounces will be sufficient; and the operation can be repeated in a week or so if it is found the first operation has been of use. When the trocar is withdrawn the puncture should be covered over by a compress, and fixed with plaster and a bandage, and perfect rest enjoined for a few days after the operation.

*Concussion of the Brain* may follow a severe blow or fall from a height, producing more or less contusion of the brain. The result may be sudden interruption or disturbance of the functions of the brain, which may last for a short time followed by improvement and recovery, or in other severe cases the functions are not only suddenly interrupted, but profound insensibility sets in ending in coma which is occasionally fatal. For practical purposes it is therefore understood, we have two stages: In the first, the symptoms are all more or less slight, although apparently alarming. In the second, the symptoms are necessarily severe and really alarming.

Owing frequently to the meagre account we get of the history of such accidents, it is sometimes difficult to distinguish concussion from compression of the brain, and moreover, the early symptoms appear the same in each case, although if carefully considered, they are not really so. To aid you in making your diagnosis, it may be useful to enumerate the symptoms under both heads:—

## CONCUSSION.

1. Symptoms come on at once after the injury.

2. The pupils are generally contracted, and in the first stage sensible to light, lids may be open and movable.

3. The skin is cold and clammy, wrinkled, resembling the cutis anserina or goose skin.

4. The breathing is sighing, and apparently very weak and noiseless.

5. The pulse is weak, frequent, and irregular, and thready.

6. Partial consciousness in first stage is present, and patient can be roused to answer questions when roughly spoken to.

7. There is frequently vomiting which is considered a favourable sign.

8. Patient retains partial power over bladder, and can expel its contents.

9. The sphincters are relaxed, and there is generally involuntary passage of fæces.

10. The patient can swallow with difficulty, and the power to do so is seldom if ever lost, except in most aggravated cases.

11. Patient can generally move the limbs, and when

## COMPRESSION.

1. Symptoms may come on at once or in the course of a few hours or days after the injury.

2. The pupils are generally widely dilated and insensible to light, and lids are generally closed.

3. The skin is hot and sweating.

4. The breathing is stertorous, noisy and whiffing.

5. The pulse is full, strong, slow and labouring.

6. Complete suspension of consciousness, patient cannot be roused, no matter how roughly spoken to.

7. Vomiting seldom, if ever seen.

8. Complete paralysis of bladder, and urine must be drawn off twice a day by means of a catheter.

9. The sphincters are closed, and are hard to be moved even with purgatives.

10. The patient cannot swallow, and the power to do so does not return for many days.

11. Patient is paralysed on one side of body, and

generally at the side opposite to the injury in the head.

12. There may be no external injury to the head present.

12. External injury to the head frequently present.

From this table it will be seen that the symptoms and signs of concussion vary according to the extent of the injury. If a slight fall has been sustained, fainting followed by giddiness and vomiting may be the only signs present. If, however, the injury has been of a graver nature you will then have unconsciousness lasting for a short time. You will notice surface cold and pale, the contracted pupil, sighing, breathing weak, frequent and irregular pulse, involuntary passage of fæces and urine. When patient is loudly spoken to he may answer in a very incoherent manner, sinking back quickly to his semi-unconscious state. In the majority of cases the diagnosis can be made out very clearly, but in some exceptional cases it must be borne in mind that a case of concussion might be converted into a case of compression in a very few hours owing to intra-cranial extravasation of blood, or still later on by the formation of pus. Conditions which in all probability will induce stertorous breathing, and thereby clear up the doubt that existed.

*Treatment for Concussion.*—Place the patient in a warm bed if the symptoms are severe, and shave the head and ensure perfect rest and quietude for the patient in a dark or very subdued light. Exclude all visitors and anxious friends. Apply hot bottles or jars to the feet, a layer of flannel being interposed. Endeavour to revive in every way the condition of the nervous and circulatory systems, but do not attempt to induce reaction too rapidly or too briskly for fear of bringing on inflammation. Apply gentle friction to the surface of the body with the hand so as to stimulate the cutaneous circulation. Sinapisms of mustard may also be applied to the calves of the legs and warm drinks administered. When reaction has set in, which may be indicated by vomiting and by the surface of the body becoming warmer, it is then the duty of the surgeon to prevent reactionary inflammation of the brain and membranes. This may be done by enforcing perfect rest, by applying cold evaporating spirit lotions to the shaved scalp, or ice broken up in a bladder. Give blue pill or calomel in repeated doses of two or three grains, three times a day, by the mouth until satisfactory purgation is produced, or rub in mercurial ointment into each axilla, say ten grains at each application. Stimulants should not be given. If symptoms continue, leeching at the back of the neck or behind the ears should be at once tried. In apparently chronic cases a blister or seton applied to the back of the neck is often of the greatest service. In all cases of concussion watch the case and symptoms most carefully, and the result of each.

*Compression of the Brain* signifies pressure on the brain, and may be produced by three causes, viz., 1st. Foreign bodies such as depressed bone in fracture of the skull, bullets in gun-shot wounds, &c., &c. 2nd. Extravasation of blood from extensive intra-cranial hæmorrhage. 3rd. The formation of pus. As the symptoms of compression have already been given as well as the treatment for the removal of depressed bone, intra-cranial hæmorrhage or suppuration when considering the operation of trephining, it will be sufficient to recapitulate the directions already given. The patient should be placed in a warm bed. Head should be shaved and carefully examined for fracture. Cold applied to head if no fracture is present. Mustard to the calves of the legs, a drop of croton oil in a bit of butter placed on the back of the tongue to produce free purgation. If this plan is not effectual give a good turpentine enema. Draw off the water twice a day. Watch and treat each symptom as it arises, and if symptoms of undoubted local pressure be present, the operation of trephining should be performed without delay.

**Wounds of the Face.**—Very frequently occur as the result of falls, blows, or stabs with sharp cutting instruments. These are treated exactly in the same way as wounds elsewhere are treated. The wound should be well cleared of clots of blood and other foreign matters, and the edges of the wound brought merely together with very fine sutures or plaister. Wounds or incisions made by the surgeon for removal of tumours, &c., heal as a rule very quickly, and they should, therefore, be brought together as soon as possible with plaister, sutures, or hare-lip pins, so as to prevent deformity remaining. When incisions have to be made, care should be taken so as to make the incisions where feasible in a line with the wrinkles and lines of the face, so as to hide the cicatrix that may follow. All wounds, whether large or small, are liable to be followed by erysipelas: care therefore, should be taken to keep the patient on a strict antiphlogistic régime with the bowels well cleared out for the first few days after the receipt of the injury, and the wound dressed with cold water dressing. In cases where abscess and diffuse suppuration occur arising primarily as the result of injury, such collections of matter should be opened early, and such punctures should always be made in a direction of the lines of the face. Wounds of the cheek may be complicated with fracture contusion, or Stevno's duct of the parotid gland may be wounded or torn, and salivary fistula follow, with weeping of the saliva on the cheek, either from the gland itself or from its duct. An incision should be made on the inside of the cheek so as to direct the flow of saliva inwards and every thing done so as to encourage the external opening on the cheek to heal. The usual agents for this purpose are stimulating lotions, pressure, actual and potential cauterisation.

**Cuts and Wounds of the Lips.**—These may be brought together after all hæmorrhage is arrested with hare-lip pins and twisted suture. Care must be taken to pass the first pin through the whole thickness of the lip down to the mucous membrane but not through it, and if hæmorrhage is going on which is sometimes profuse, the needle or pin should either transfix the bleeding vessel or pass close to it so as to compress it. The pin should also be passed close to the red margin of the lip or rather close to the line where the mucous membrane joins the skin. The edges of the incision having been evenly brought together and cleansed from all clots, the part should be gently painted over with collodion or a solution of gutta percha dissolved in chloroform so as to exclude air. The part must be carefully dried beforehand with a towel or the plaister or collodion will not adhere to a wet surface.

In some cases it is advisable, with the object of lessening the size of the resulting scar, to introduce very fine silk or silver interrupted sutures, or a very useful inexpensive and non-irritating substance used for sutures is the fine gut that is purchased at a fishing tackle shop. When sutures are applied they may be removed in three or four days; the pins may also be removed about the same time, they should not, however, be removed if union has not taken place, the scab that remains should not be disturbed until it falls off of its own accord.

**Injuries to the Eye.**—When the lids are torn or lacerated the edges of the wound should be carefully and quickly adjusted, and kept in their place by very fine sutures, so as to prevent deformity. If the tarsal cartilages are implicated a fine suture should be passed through the injured part and evenly adapted, a pledget of lint, steeped in cold water, should then be placed on the lids and the eye kept closed for some two or three days, the bowels at the same time being well cleared out and a mild antiphlogistic régime enjoined.

**Contusions to the Eyelids** produce great ecchymosis or what is called *black eye*, which can be in a great measure prevented if seen at once, by the local application of intense cold, ice or cold steel, or evaporating spirit lotion.

**Injuries to the Globe of the Eye.**—Sudden blows to the

eye may displace the crystalline lens forwards or backwards. If it be displaced forwards into the anterior chamber of the eye and causes no pain, and if the patient be young, no treatment need be adopted save a drop of atropine placed in the eye, and the eye kept closed, the dislocated lens may float back through the pupil again. If, however, the lens gives trouble in the way of pain and inflammation, and the patient over the middle period of life, the dislocated lens should be removed without further delay by the operation of extraction. It may be mentioned that the slightest tap to the globe of the eye may at times dislocate the lens, in fact the cause may be so slight that the patient is unaware of receiving any injury to the eye.

**Rupture of the Anterior Portion of the Globe of Eye.**—Such an injury may follow a penetrating wound or sudden blows inflicted directly while the eye is open. In mineral water manufactories it has happened that, while corking soda-water bottles the cork has been forcibly expelled into the eye, rupturing the cornea, followed by evacuation of the aqueous humor, displacement forwards of the iris, and occasionally hernia of the iris through the ruptured cornea.

**Treatment.**—If the aqueous humor alone is evacuated without further complication, the eye should be carefully examined to ascertain the exact position of the iris. If in its place the eye should be opened in a strong light so as to cause the pupil to contract, or a disc of calabar bean inserted under the eyelid so as to hasten the process, a small quantity of charpie placed on the lids, which are kept closed by slips of court or adhesive plaister or a Liebreich's eye bandage applied, and the strictest antiphlogistic régime enforced so as to anticipate inflammation. If the iris is displaced and protruded through the corneal opening, an attempt ought to be made to return it. A drop of atropine introduced into the eye may assist in returning it, if this cannot be done the prolapsed portion had better be left alone, as in all probability it will slough off in a day or so. If snipped off with a scissors further protrusion will most likely occur.

**Foreign Bodies penetrating into Globe of Eye.**—It not unfrequently happens that portions of percussion caps, gunpowder, or grains of shot may traverse one or other eyelids and then pass deeply into the globe of the eye. When such an accident has occurred the question arises what is best to be done, for it must be remembered that immediate blindness is sometimes followed by the presence of a grain of shot deeply embedded in the eye. If the grain of shot is merely lodged in the sclerotic where it can be seen or felt, it must be at once removed. If, however, it has passed into the eye deeply, a search for it is out of the question, if it causes no pain, irritation, or derangement of vision it may be allowed to remain in the hope that it may become encysted. If, on the other hand, pain, inflammation, and derangement of sight set in, the injured eyeball should be enucleated without further delay so as to save the sight of the other eye from being lost through a sympathetic inflammation. Mackenzie mentions on this point "an attempt to remove a lead pellet from the eye when it has passed either through the cornea or the sclerotic into the vitreous body, I should suppose would be fruitless and likely only to irritate the eye and lead to inflammation. Left in the vitreous humor the pellet will probably sink down in contact with the retina. Vision, as far as I have seen, is totally destroyed by such an accident, and I have never known of the foreign body coming to the surface so that it might be extracted. In cases of explosion of gunpowder all particles should be carefully removed from the eye by a stream of water from a syringe.

**Foreign Bodies Embedded in the Conjunctiva.**—Removal of small particles embedded in the conjunctiva: small portions of coal, iron, cinders, and other substances frequently get firmly embedded in the conjunctiva, every movement of the eyelids only tends to fix the foreign body more firmly in its abnormal position. Sometimes the particle is so small that it can hardly be seen although

the patient is fully conscious of its irritating presence, besides the congested condition of the conjunctiva and the great lachrymation that very soon follows, indicates the presence of some irritating substance.

*Treatment.*—Place the patient sitting on a chair in a strong light, or lying on the back on a couch or sofa in a good light, the upper eye-lashes should be gently grasped and the upper eyelid slightly moved from side to side, and possibly by this motion the particle may float down, being carried by the flow of tears to the inner canthus, and there detected, if not, the upper eyelid should be inverted, which can easily be done by means of a fine probe placed parallel and close to the margin of the eyelid, while the eye-lashes are gently drawn between the finger and thumb over the probe, if it rests on the internal surface of the lid, the corner of a handkerchief or a piece of dry blotting paper, or the end of a quill toothpick may be used to dislodge it, or a stream of water directed against it from a syringe is very useful; occasionally, if the particle is deeply embedded in the cornea it must be dislodged by means of a curette or gouge passed under it so as to lift it off the conjunctiva. When it is removed the eye should be gently syringed with warm water, or castor oil introduced into the eye is a very soothing remedy after such irritation. In some cases the irritation left by the temporary presence of some foreign particle may persuade the patient that the particle still remains in the eye. This should be quickly cleared up for the prolonged poking at the conjunctiva in search for an imaginary foreign body will only make matters worse. Forcibly sneezing for two or three times in succession has been frequently known to dislodge particles under the eyelids.

*To Remove Mortar, Lime, or Chemical Substances Accidentally introduced into the Eye.*—No substance is so destructive as lime accidentally introduced in any quantities into the eye.

*Treatment.*—Immediately evert both lids, and the eye well syringed with water so as to wash away all particles with as little delay as possible, then wash out the eye with weak vinegar and water. If acids are introduced syringing with water affords the best chance, and afterwards a weak solution of bicarb. of soda, two or three grains to the ounce of water, will neutralise the effects of the acid.

(To be continued.)

## HISTORY OF THE PROGRESS OF LARYNGOLOGY FROM THE EARLIEST TIMES TO THE PRESENT.

By GORDON HOLMES, M.D.,

Physician to the Municipal Throat and Ear Infirmary, London; Consulting Physician to the Sheffield Ear and Throat Hospital.

Il importe beaucoup de connaître l'histoire de la science à laquelle on s'attache.—Boerhaave.

### EPOCH I.—THE PRE-LARYNGOSCOPIC AGE.

(Continued from page 145.)

*Physiology.*—Three physiological questions of leading importance were greatly advanced, if not finally determined, during this period, *i.e.*, the action of the intrinsic laryngeal muscles, the functions of the nerves of the larynx, and the precise method of formation of the ordinary (chest) vocal tones.

Although in a general way the action of the laryngeal muscles had been correctly stated by various authors previous to this period, the subject was apprehended very inconclusively and imperfectly, and the views held rested on no clear demonstration. Hence at the beginning of the present century two anatomists could scarcely be found in near accord on this question.

In 1796 S. T. von Sömmerring, (1) for example, the principal anatomical writer of his time, whilst stating correctly the action of the lateral crico-arytenoids, yet counts the thyro-arytenoids and crico-thyroids dilators of the glottis. (2)

Francois Magendie (1783-1855), Professor of Medicine, &c., at Paris, made some valuable experiments (3) in 1812 on the physiology of the larynx, primarily as to the purpose of the epiglottis. He removed it completely in dogs and several other animals, and found not the least consequent difficulty in swallowing either solids or liquids. By making an opening in the throat he saw that the larynx closed completely during deglutition, and this act was scarcely interfered with on section of both recurrens. But when both superior nerves were cut the cartilaginous glottis was not shut, though not until the four nerves were divided did the animals really experience great difficulty in swallowing. He also examined into the action of the crico-thyroid muscle, and concluded, in opposition to all previous authority, that it raised the cricoid to the thyroid cartilage.

In 1829 Robert Willis, (4) of Cambridge, took up the subject of the use of the muscles, and treated it with a mechanical exactitude not before reached. He first proceeded to examine the mechanism of the crico-arytenoid joint, and on his definite recognition that the motion of the arytenoid cartilages is chiefly one of rotation, the prime difficulty of the question may be said to have been surmounted. The confusion that so long prevailed was, in fact, due principally to the slowness of the older anatomists to concede any but right-line movements to these cartilages. By a carefully studied application of the laws of mechanics as to the resultant of various forces acting on a point, Willis showed (A) that the crico-thyroid muscles must necessarily produce tension of the vocal bands; (B) that the thyro-arytenoids would have the reverse effect and relax the same ligaments; (C) that the posterior crico-arytenoids rotate the arytenoid cartilages so as to separate the vocal processes and with them the vocal bands; (D) that the lateral crico-arytenoids, on the contrary, rotate those cartilages until the vocal processes touch anteriorly, thus bringing the vocal bands into apposition; and finally (E) that the transverse arytenoid muscle approaches the bodies of the arytenoid cartilages so as to close the glottis completely when acting in conjunction with the lateral crico-arytenoids. These demonstrations of Willis, though clear and incontrovertible, were not accepted universally for many years. The text-books were filled with conflicting and erroneous views maintained by prejudices in favour of baseless but authoritative theories. (5) Willis's views, however, crept gradually into all the standard authors, and after the practical verification of them afforded by the next experimentalist were soon fully established by common consent.

In 1841 F. A. Longet, (4) Professor of Physiology at Paris made an important series of experiments to discover the action of the muscles of the larynx. He proceeded by severing in dogs the nerve filaments supplying each muscle and galvanising the cut ends immediately after death. By this means the various muscles were thrown into contraction separately at the will of the operator. The only apparent exception to Willis's calculations occurred in the case of the thyro-arytenoids which were only determined to give "more stiffness to the vocal cords, to render them more vibratile, and to swell them a little so as to diminish slightly the opening of the glottis." In addition, he observed that the crico-thyroid muscle drew the cricoid cartilage up to the thyroid. The only flaw in these investigations is that Longet does not seem to have taken into consideration the *consortant* action of two or more pairs of muscles.

About 1812 our knowledge of the functions of the pneumogastric nerves was much extended by J. J. C. Le Gallois, (7) of Paris. Incidentally in the course of this inquiry the motions of the glottis during respiration were discovered. Previous physiologists had ascertained vaguely that section of these nerves was fatal, but it remained for Le Gallois to distinguish the immediate causes of this result from those more remote. By vivisectional experiments he proved that the first cause of death was suffocation through paralysis of the dilators of the glottis, consequent on abrogation of function of the recurrent nerves. (8) In order to demonstrate this point to the Faculty of Medicine of Paris, "I took," says he, "some rabbits about two month old, in which I detached the larynx from the os hyoides and the adjacent parts without wounding its proper muscles or the recurrent nerves. Then I inclined it sufficiently towards the chest to make visible the opening of the glottis. This aperture was plainly round, or at least slightly oval from above downwards (the larynx being supposed in place and the animal standing), especially during inspiration. This fact being well

ascertained, I cut both nerves of the eighth pair at the middle of the neck; instantly the two arytenoid cartilages approached each other and the thyroid, the opening of the glottis diminished and presented, instead of a hole almost round, an unvarying slit directed from above downwards. In other rabbits of the same age the arytenoid cartilages and the glottis had, before section of the nerves, movements corresponding to those of respiration; at each inspiration the glottis enlarged, and became round; then, during expiration, it contracted itself by the approach of the arytenoid cartilages to each other and towards the thyroid in regular succession. (9) But after section, whether of the eighth pair or of the recurrents, it remained immobile and narrowed to a slit. It must be remarked that these movements of the glottis do not take place, or at least are not well marked, unless the breathing is a little hampered." Le Gallois found that section of the recurrent nerves, whilst being almost immediately fatal in animals a few days old, was less and less influential in causing death with advancing age, so that in adults, especially dogs, loss of voice was almost the only inconvenience felt. In all cases, by performing tracheotomy the animal could be kept in good health for an indefinite length of time. With the postponed fatal issue on division of the trunks of the vagi we are not here concerned.

About 1832 Marshall Hall discovered the excito-motor functions of the nervous system, that is, the phenomena of reflex action, thus transferring the origin of certain muscular movements from the nervous centres to their periphery, or from the domain of volition to that of involuntary motion. "The influence of the stimulus," says the author, (9) "is carried along an excitator and incident nerve to the medulla oblongata or medulla spinalis, and it is reflected thence along other reflex or motor nerves." In this excito-motor system, as applied to the larynx, Hall (10) viewed, in 1841, the superior laryngeal nerves, principally the *incident, excitator nerves*, the inferior laryngeals, as principally the *reflex and motor*." The cause of coughing on irritation of the laryngeal mucous membrane, and of closure of the larynx in deglutition and vomiting, formerly vaguely explained as voluntary acts, is thus disclosed.

About 1838 Le Gallois' researches as regards the laryngeal nerves were much extended by John Reid, (11) Professor of Medicine at St. Andrews. This observer showed conclusively that the superior nerve supplies sensation to the larynx, and the recurrent motion, except in the case of the crico-thyroid muscle. "When the superior laryngeal nerve," he relates, "is laid bare in a living animal and pinched with the forceps, the animal gives indications of severe suffering, while on repeating the same experiment with the inferior laryngeal the animal seldom gives any indication of suffering pain. When an opening is made into the trachea and a probe introduced through it into the interior of that tube and passed upwards, it excites little or no uneasiness until it reaches the larynx, when violent paroxysms of coughing and signs of great uneasiness immediately follow. The division of the inferior laryngeal nerve has no effect in diminishing the severity of these paroxysms of coughing or in quieting the struggles of the animal, while they instantly cease on cutting across the internal branch of the superior laryngeal nerves..... We found that on applying different excitants to the superior laryngeal nerve before it gave off its external branch in several animals immediately after death, that the crico-thyroid muscle was thrown into powerful contraction and the cricoid approximated to the thyroid cartilage, while all the muscles attached to the arytenoid cartilages remained quiescent. On irritating the inferior laryngeals all the latter muscles were thrown into contraction, and as the force of those muscles which close the superior aperture of the larynx preponderates over that of those which open it, the arytenoid cartilages were drawn forwards and inwards, and the superior aperture of the larynx was closed. Reid's conclusion is that "the superior laryngeal nerve furnishes one only of the laryngeal muscles (the crico-thyroid) with motor filaments, whilst it supplies nearly all the sensiferous and incident filaments of the larynx, and also some of those distributed to the pharynx and back of the tongue, so that it is mostly composed of sensiferous and incident filaments. The recurrent nerve furnishes incident and sensiferous filaments to the greater part of the trachea, to the cervical portion of the oesophagus, a few to the mucous surface of the pharynx, and still fewer to the larynx; it supplies the motor filaments of the cervical portion of the oesophagus, and of all the muscles which are attached to and move the

arytenoid cartilages, and is chiefly composed of motor filaments." In 1837, as Reid remarks, John Hilton, (12) of Guy's Hospital, had, from anatomical considerations alone, announced views as to the laryngeal nerves very nearly in accordance with these experimental results.

Another important point as to the innervation of the larynx is the question of the ultimate source of the various motor and sensory filaments embraced in the common trunk of the pneumogastric. Much discussion and experiment were devoted to this subject by neurologists for more than twenty years. In 1821 Charles Bell (13) and Magendie discovered that the anterior and posterior roots of the spinal nerves had different functions, the former being motor and the latter sensitive. Inspired by this fact T. L. J. von Bischoff, (14) of Darmstadt, essayed, in 1832, to prove by various arguments and experiments that the vagus is essentially a spinal nerve, all its motor filaments being derived from an anterior root, viz., the spinal accessory. His views prevailed at the time, and physiologists had almost settled down into the belief that the pneumogastric was purely sensitive before meeting the accessory portion, when, in 1844, Claude Bernard (15) reopened the inquiry, refuted Bischoff, and finally solved the problem. By the aid of various vivisections he obtained results which demonstrated that the vagus is a mixed nerve from its origin at the restiform body, but that the greater number of its motor filaments are derived from the spinal accessory. And, as regards the larynx, there is a marked distinction between the functions ruled by the two sets of motor-fibres, i.e., when the spinal accessory is cut the animal does not perish from closure of the glottis in the manner shown by Le Gallois. On the contrary the passage is maintained fully dilated by unimpaired action of the posterior crico-arytenoid muscles. But the other intrinsic muscles of the larynx are paralysed almost completely, even the crico-thyroid, the difference in the innervation of which is thus shown to be only apparent. Thus the voice is lost, but not absolutely, the animal can still emit weak, short vocal tones. The practical inference is, therefore, that the spinal accessory is the proper nerve of phonation, and that from the primitive pneumogastric emanates the power which presides over the respiratory office of the glottis. The latter motions, it need scarcely be said, are in great part involuntary, whilst the former are altogether voluntary.

With respect to the formation of the voice some credit is due to R. J. H. Dutrochet (16) who, in 1806, repeated the experiment of Ferrein with more accuracy, and insisted on the analogy between the action of the vocal bands and that of the vibrating reeds used in musical instruments. He was the first who tried to estimate the proportion existing between rise of pitch and tension of the vocal bands by attaching various definite weights to them. At the same time he worked out a clearly conclusive refutation of Ferrein's hypothesis that the larynx acted as a stringed instrument.

In the course of his other experiments Magendie (17) observed the state of the vocal bands in phonation through the openings he made in the throats of dogs, &c. He saw that they vibrated like reeds, for deep tones in their whole length, and for high notes perceptibly only at their posterior part. The cartilaginous glottis appeared to be always tightly closed so as to take no part in generating the sound.

The received theory as to the source of the sound produced by a reed or elastic tongue vibrating at an aperture which it fits with more or less exactitude, was originated or at least first clearly formulated by J. B. Biot, (18) professor of physics at the College of France. He stated that the sound arose from the series of aerial puffs, pulses, or shocks caused by the reed alternately opening and closing the aperture as the stream of air passed through. But the demonstration of this view was wanting until the invention in 1825 by Cagniard de la Tour of the well-known acoustic machine called the siren. This instrument, which consists of a disc perforated near its outer edge by a circle of holes through which a blast of air is impelled during rotation, proves that by a series of puffs of air a musical note can be formed, varying in pitch according to the rapidity of the puffs. Many years elapsed, however, before physicists generally recognised that the siren disclosed the true principle of the action of reeds. Some slight objections were long maintained with pertinacity, the chief one being that the reed need not close the hole perfectly in order to be capable of creating a note. But in this case it is suffi-

ciently obvious that the varying capacity of the aperture would still cause shocks in the stream of air, though of less strength, and that the sound would consequently only be weaker, points fully established in practice. Biot and those who supported his theory saw, of course, clearly the analogy between the siren and the action of the vocal bands, which alternately receding from and approaching each other whilst vibrating, divide the current of the breath into a succession of puffs.

About 1835 Johannes Müller, (19) professor of physiology at Berlin, made an exhaustive series of experiments on the human larynx and artificial imitations of it, and again verified in the most practical manner the discoveries of Ferrein. He produced graduated extension of the approximated vocal bands with the most careful and ingenious arrangements, and by progressive small additions to the weights he attached to them obtained a chromatic scale of nearly two octaves. He showed that the vocal bands followed the laws of vibrating strings as to the ratio between tension and pitch, that is, by quadrupling the stretching force or weight a rise of an octave would be obtained, &c. He also tried the effect on the laryngeal tones of tubes of various lengths added both above and below the vocal bands, with the result of proving that, though resonance could be thus modified, alterations of pitch could not be effected by pipes at all similar in capacity to the actual vocal tubes. Nevertheless, Müller was one of those who could not reconcile his own views with the elucidations afforded by the siren, but, on the other hand, he did not succeed in convincing even himself that the sound of reeds arose from their independent vibrations. Excepting, however, the falsetto voice, it may be considered that the main question in laryngeal acoustics, though not ascertained beyond controversy, were at this time satisfactorily determined in the eyes of all temperate scientists.

The mechanism of the falsetto voice, viz., those high sounds which can be emitted after closure of the cricothyroid space renders further tension of the vocal bands impossible, has always been an obscure matter, so much so that several observers have argued that this vocal scale is not formed in the larynx at all. It would be useless to recount the various explanations offered on this subject at a time when, even if approaching the truth, they were incapable of any tangible proof. In 1835 the merit, however, may be allowed to Carl Lehfeldt, (20) graduate at Berlin, for insisting that the tones emanated from the larynx alone, and for the suggestion that they were formed by the vibration being restricted to the edges of the vocal bands. He was led to this opinion by observing in experiment that a gentle current of air, by giving rise to limited vibrations, produced a note a third, fifth, or even an octave higher than when a full blast was directed against the vocal bands. Müller afterwards corroborated him in this point, but the explanation can only be received as affording a clue to the truth, pitch not being governed by varying the force of the breath-current in the living subject.

**Pathology.**—The chief pathological achievement of this period was the differentiation of the various kinds of destructive ulceration of the larynx as commonly met with. This work progressed slowly for more than half a century before it was brought to a conclusion. The first special effort in this direction was made in 1790 by Marc Antoine Pétit, (21) of Montpellier, who debated the subject with considerable acumen under the title of "laryngeal phthisis." The word phthisis at this date was only beginning to have the restricted meaning as regards lung disease that it possesses in the present day, and was applied to almost any wasting affection. Hence "laryngeal phthisis" was then a very inclusive term and implied no necessary relationship with pulmonary tuberculosis. (22) With Pétit the malady includes practically every severe chronic disease of the larynx, its chief cause is syphilis, and it is very frequently associated with consumption of the lungs. The diagnosis is, therefore, facile, he thinks it may possibly be confounded with *laryngitis membranacea*, i.e., croup, but that the only real difficulty lies in distinguishing it from polypus of the larynx, the symptoms of which he seems well acquainted with. The abuse of mercury and chronic catarrh of the throat are, according to Pétit, sometimes the origin of laryngeal phthisis, but he appears to have no suspicion that many cases, such as he has in view, may really be examples of cancer.

In 1802 Amand Sauvée, (23) and in 1806 L. T. Laigleat,

(24) both students at Paris, treated of laryngeal phthisis in their graduation essays. Each appears to be ignorant of, or at least to ignore, any previous efforts of the same nature as their own, and their treatises are in most respects similar to that of Pétit and to each other. The three essays seem to collect in fact the floating ideas of the profession on the subject at that period, and illustrate them by a few original cases. In the triad, however, a step in advance must be ascribed to Sauvée for proposing the question precisely as to whether laryngeal phthisis could exist without pulmonary phthisis, and for solving it affirmatively by the example of certain cases.

During the next two decades ulceration of the larynx was treated of by several French and German authors, but without sensible advance beyond that of putting on record a larger number of cases. Towards the end of this time, however, the conception of tubercles being developed in the mucous membrane of the larynx and producing ulceration by their softening, seems to have been first definitely entertained. In 1824 this idea is for the first time clearly expressed and considered seriously by C. J. Pravas, (25) of Paris, in his graduation thesis. In 1825 the celebrated P. C. A. Louis, physician to the Hotel Dieu, &c., as the result of frequent observations of autopsies in pulmonary phthisis, expressed the decisive opinion (26):—"Ulcerations of the larynx, and especially those of the trachea and epiglottis, must be considered as lesions proper to phthisis." Nevertheless in his researches he perceived no tubercles in the larynx, and hence concluded that the disease was of an inflammatory nature, caused by an irritating or excoiorating action of the sputa discharged from the disintegrating lungs. The ulcers, in fact, which by some chance exclusively came under the notice of Louis, were those of shallow, extensive erosions, chiefly found on the posterior walls of the trachea and epiglottis, apparently in the track of the expectorated mucus. Yet in his observations of this lesion, as well as in his etiological conceptions, Louis was anticipated, though only in some brief and casual remarks, as early as 1808 by the renowned F. J. V. Broussais, (27) professor of medicine at the Val-du-Grace, and author of the once all-dominant doctrine of Essentiality.

The numerous and continuous memoirs relating to laryngeal phthisis with their marked inconclusiveness induced the Academy of Medicine of Paris, in 1836, to propose "The History of Laryngeal Phthisis" as the subject of competition for a prize. This prize was taken by two young investigators who had already begun to work conjointly in order to elucidate the disease, Armand Trousseau, afterwards physician to the Hotel Dieu, and J. H. Belloc. (28) These authors executed their task with vigour and penetration, and presented a scheme of laryngeal pathology in which the chief diseases of the organ were distinguished scientifically, and their phenomena illustrated by well observed cases. Their inferences were drawn from over sixty instances included in their treatise, half of which came under their own observation. Trousseau and Belloc made four species of laryngeal phthisis, viz., (A) *simple* (severe or hypertrophic chronic laryngitis), (B) *syphilitic*, (C) *cancerous*, and (D) *tuberculous*. They did not, however, discover tubercles in the larynx, but advocated their occurrence by analogical reasoning, e.g., "If the tubercular diathesis can invade the crypts of the ileum . . . why should we hesitate to admit that the same thing can happen as regards the larynx, which is a part of the respiratory apparatus, and consequently ought by its connection with the lungs to be still more exposed to invasion of tubercular matter." (29) Of cancer they could only give a single example.

The inaptness in finding tubercular deposit in the laryngeal mucous membrane at first led most of those who searched for it to deny its existence in that situation. The earliest investigator who asserted that he had seen it was J. B. Barth, (30) professor of medicine at Paris. In 1839 he stated:—"In consumptive patients we find often enough that the mucous membrane is raised in various points by small bodies of a dull or yellowish white colour, over which the membrane tends to become inflamed and ulcerated to give passage to the tubercular matter amassed underneath." Nevertheless, for more than a quarter of a century after Barth's statements, the chief names among French pathologists, with a few exceptions, concurred in the denial of laryngeal tubercle.

The doubts which reigned so long in France never gained much ground in Germany, for, as early as 1842, Carl

Rokitansky, professor of pathology at Vienna, whose word was law with almost all his countrymen, affirmed (31) most circumstantially the deposit of tubercle in the larynx. "Tubercle of the air-passages," he writes, "is, to speak generally, a very frequent phenomenon. . . . It is mostly found in the larynx, . . . but as primitive and independent so extremely seldom that its presence as such has been altogether denied. It almost always follows lung tuberculosis after this latter has made some progress. The site of the tubercle is almost constantly, and again exclusively, the mucous membrane and the submucous connective tissue over the arytenoid and the contiguous cartilages; yet it is found exceptionally in other places also, and on the front of the epiglottis. It is deposited in the submucous connective tissue either as a gray granulation, or infiltrates the mucous membrane as a yellow mass of tubercle of cheesy brittleness. It occurs commonly in both forms, but in the latter it is particularly rapid in softening and ulceration. Soon there arises from the dissolution of the gray granulation a small round ulcer, from the size of a millet seed to that of a lentil, with an everted hard edge, which coalesces with others in the vicinity, and hence arises a second form of ulcer, viz., an irregular one with an indented margin and a cellular, callous, and thickened base, both of which become the seat of secondary deposit of tubercle." Rokitansky then goes on to note the progressive ravages of these ulcers, so that they extend over the whole larynx, epiglottis, and even spread to the soft palate, giving rise at the same time to deep suppuration and necrosis of the cartilages. He further remarks that by perforating outwards they may occasion emphysema of the neck. With this description, so minutely exact notwithstanding the early date at which it was made, and which cannot justly be said to have since been surpassed, the pathological history of laryngeal phthisis may be considered practically to terminate.

## Clinical Records.

### LARGE MULTILOCULAR CYST OF THE RIGHT OVARY; SMALL CYST ATTACHED TO THE LEFT BROAD LIGAMENT; OVARIOTOMY; RECOVERY IN EIGHT DAYS.

Under the care of DR. J. THIRIAR.

B. G., æt. 41, came under treatment on account of a large abdominal tumour on March 7th. She was a badly-nourished woman; had had eight children, the last three years ago, since when she had been quite regular until October, 1884, when the periods ceased. She noticed the abdominal enlargement first in March of the same year, the growth being on the right side at the commencement, the patient regarding it as an indication of pregnancy. It rapidly increased in volume, and at the end of February its dimensions reached such proportions that an immediate operation was considered necessary by the physician attending the case. The operation was not, however, performed until March 8th, but in the interval an endeavour to afford relief to urgent symptoms by puncturing the tumour was made, at a point above the navel on the right side, where a fluctuating point could be recognised; and half a bucket-full of dense, thickened colloid liquid withdrawn. At the time of the operation the general state of the patient was tolerably good, but she was very much wasted, and had a yellow look. The extremities were infiltrated with fluid, and the abdomen yielded the following measurements:—From the xiphoid to the pubis, 25·6 inches; from the xiphoid appendix to the umbilicus, 11·6 inches; from side to side between the anterior superior iliac spines over the umbilicus, 30·4 inches. The belly presented an unusual appearance, being very much lengthened and as though divided into two parts by a transverse furrow. The tumour was apparently uniform, and on pressure it could be felt to invade all parts of the abdomen as far as the epigastrium, and more or less indurated points could be made out. Succussion revealed a shaking of ascitic fluid, which, however, could only be perceived at the upper part of the tumour, and percussion demonstrated the presence of the intestine in the flanks. The uterus was small and moveable, the cervix short, and the external os admitted the pulp of the examining finger. The perineum showed signs of laceration, and the rectum projected towards the posterior wall of the vagina.

The operation of ovariectomy was performed by Dr. Thiriari on the 8th of March at 11 a.m., having been preceded at 10 a.m. by the injection of the following mixture:—Laudanum, 30 drops; chloral, 30 grains; and water, 50 grammes. Dr. Thiriari has great faith in the efficacy of this preliminary treatment, and attributes to it in great part the success he has obtained, twenty-three cases of ovariectomy in which it was observed having all recovered well. Complete antiseptic precautions were observed during the operation, which occupied in all twenty-three minutes. The first incision extended from the umbilicus to the pubis, and the cyst having been opened it was found to be extensively adherent to the abdominal wall; and in the attempt to separate the parietal peritoneum from the wall of the cyst, the former membrane was torn through to an extent of two inches or more. The mistake was, however, at once perceived, and the primary incision extending above the navel to the point where ascitic fluid had been previously recognised, and which was consequently free from adhesion. The operator was thus enabled to separate the upper part of the cyst from the parietal peritoneum. Even then, however, the tumour could not be removed on account of its size, and to permit the accomplishment of this stage of the proceeding it was incised, and the hand of the surgeon plunged into its interior, all the obstacles encountered being freely broken down, the escaping liquid being meanwhile prevented from entering into the cavity of the abdomen. Being thus much reduced, the growth was then easily extracted. The pedicle was large, and was tied with a double ligature. A small cyst proceeding from the left broad ligament was also removed, and the remaining stages of the operation performed in the usual manner, subsequently to which a morphia injection was practised and some champagne administered. On the sixth day subsequently the patient was able to get up, and returned home on the 19th March. Recovery was

rapid and continuous, the highest temperature recorded being 100°. Once only, on the evening following the operation, vomiting occurred, and being attributed to the champagne, this latter was not again administered. Two days after the operation the patient eat with a good appetite, and the dressings were permanently removed on the eighth day, perfect union having ensued. The tumour presented all the characters of colloid, cystic growths.

## Transactions of Societies.

### ACADEMY OF MEDICINE IN IRELAND. MEDICAL SECTION.

CLOSING MEETING, HELD FRIDAY, MAY 29TH.

DR. DUFFEY, Vice-President of the College, and subsequently DR. CRUISE, President, in the Chair.

#### NOTES OF VISITS TO CONTREXEVILLE AND ROYAT.

DR. CRUISE, President of the Medical Section, read a paper giving an account of his visits to Contrexéville and Royat-les-Bains, with some details respecting those mineral waters, and pointing out the various cases in which they are found useful. Contrexéville, which is situated in the Vosges mountains, belongs to the class of calcareo-sulphated waters. Its water is alkaline, with a preponderance of salts of lime, aperient from sulphates of soda and magnesia, and restorative from iron and arsenic. The principal spring there is the Pavilion, the analysis of which, as given by M. Debray, is as follows:—

The effects of the Contrexéville waters are:—1st. Diuretic, 2nd. Laxative. 3rd. Tonic. The diseases in which they are found useful are principally as follows:—Chronic Affections of the Urinary Organs. Gout, especially the atonic forms. Diseases of the Liver. Nocturnal Enuresis in Children. Diabetes, especially when associated with Gout. Royat-les-Bains, which is situated in the Auvergne mountains, belongs to the class of alkaline-chlorinated waters, with the addition of salts of lithium, iron, and arsenic.

M. Lefort's analysis of the principal spring—the Eugénie—is appended:—

The effects of the Royat waters are:—1st. Stimulating to the circulation. 2nd. Diuretic. 3rd. Laxative. 4th. Tonic. The diseases in which they are found most useful are principally as follows:—All forms of Gout and Rheumatism, especially the atonic phases. Anemic and Lymphatic Affections. Affections of the Throat, Lungs, and Uterus.

The CHAIRMAN (Dr. Duffey) noticed that the President did not allude to the silica in those springs.

DR. TICEBORNE, having examined Contrexéville water, as imported, said the analysis was almost identical with that exhibited in the President's diagram, and therefore what found its way to this country was genuine. That was not always the case. It appeared from the analysis that chlorine was associated with iodide of potassium. But it was a difficult thing to prognosticate from an analysis what was the composition of the water, since chlorine was not originally associated with it. He was struck with the analysis of Royat water as regards the extraordinary amount of lithium—0.037, being about 2½ grs. per gallon. It was of great interest to see the water was so rich in that particular body. He asked had cesium and rubidium been found, there being an idea that they possess qualities similar to lithia in their action.

DR. JAMES LITTLE said he was not in a position to speak of the waters of Royat; but many years ago he had heard from Dr. Cruise of the value of Contrexéville waters in affections of the bladder. That practical piece of information had helped him to keep persons alive with bad bladders; and since then he had formed an opinion of those waters. Those to whom he gave the waters said they produced the effects Dr. Cruise had enumerated, and that they usually improved the appetite, kept the bowels open, and made people feel comfortable. In this country the waters appeared to be useful in that kind of dyspepsia occurring in people of a sallow complexion and sedentary habit connected with the diseased condition of the liver. In gallstone the waters also appeared to be useful. An old London physician had told him that he gained more benefit from gout by the Contrexéville waters than any other mode of treatment. The chief virtue of the Contrexéville waters lay in their effect on the urinary organs, especially catarrh of the bladder and stone. In catarrh of the bladder he first had had an opportunity of seeing the value of the waters. It was the case of an old man in whom catarrh had arisen in connection with imperfect emptying of the bladder through enlarged prostate. From a physician whom he met at Contrexéville he ascertained that in giving the water for stone the best plan was to give a large quantity early in the morning before breakfast, whereas for catarrh or gout the better plan was to give it in divided portions during the day. To clear away gravel, he had recommended patients to drink a bottle before breakfast. But in catarrh of the bladder he had recommended a certain portion before breakfast, luncheon, and dinner. A few months ago he saw a lady, and from the account she gave of the pain running down the thigh, he felt certain it was renal calculus. He recommended her a six weeks' course, and at the end of that time he received from her the calculus shown. With regard to Contrexéville itself, as compared with the great German baths it was rather a sad place.

DR. H. KENNEDY approved highly of Dr. Cruise's remarks. But a large number of persons were unable to visit those baths, and it was, then, well to keep in mind the work of Roberts, of Manchester, in which, by medical treatment alone, he proved that not only could calculus in the bladder be modified, but even brought away.

DR. FINNY had employed Contrexéville water in some cases of bladder affections where cystitis was a common symptom; but his experience was not as good as that of those who had spoken—in fact, he was disappointed in the results. He did not find that it gave relief to the bladder troubles, nor that it improved the condition of the water in removing the mucus, as Dr. Cruise had experienced. But perhaps in this country the habits of the patient, combined with the climate and other causes, affected the action of the water in different ways.

DR. T. E. CAHILL having also joined in the discussion,

DR. CRUISE, in reply, said they had not sufficient knowledge of the therapeutical value of silica to attach much importance to it more than to the fluorides, or fluoride of calcium. There were no traces of cesium, rubidium, or strontium in the waters, according to Debray. With regard to the chloride of lithium in the Royat water, he was correct

in the quantity given. Contrexéville was an early watering place, closing on the 15th September, after which it was not a very gay place. Dr. Kennedy's reference to Roberts' remarkable observations recalled the celebrated cures published in old times; but these were affected with soft or phosphatic calculi, and would not influence a hard calculus, such as oxalate of lime, or lithic acid. Dr. Finny was not satisfied with the waters which did not give the relief required in some cases. That was his own experience in some cases, but that was also the fate of all drugs and mineral waters. The difference in the doses for the gout proper and for cases of stone he was glad to hear.

#### PRIMARY SARCOMA OF THE RIGHT KIDNEY.

Dr. WALTER SMITH exhibited a specimen of primary sarcoma of the right kidney, and read notes of the case. The tumour weighed nearly 4 lbs., and in microscopic structure was that of a spindle-celled sarcoma. It was removed from the body of a man, aged fifty-three years, admitted into Sir Patrick Dun's Hospital, October 25th, 1884. His family history was good, and he was in perfect health until about two years ago, when he felt a slight pain in the right side, and soon after noticed a swelling. The tumour slowly increased in size, but he was able to work as a brass finisher up to a month before admission to hospital. The tumour extended from the ribs to within two inches of the ilium, and laterally about two inches to left of umbilicus. There was no ascitis at any time, and the cutaneous veins, anteriorly and laterally, were permanently enlarged, forming a visible network. The fingers could be depressed readily into the groove between the tumour and the ribs, and, notwithstanding that no evidence of intestine in front of the tumour could ever be detected, the diagnosis of malignant renal disease was easily made. The urine constantly contained a considerable amount of albumen, with some tube casts, and although usually bright and clear, always became turbid (mucin) with acetic acid. From time to time he passed, *per urethram*, curious tassel-like and vermiform fragments of fibrinous clots, mostly decolorised, and sometimes three inches in length. The man's strength very gradually gave way, and he died on April 14th.

*Post-mortem, twelve hours after death.*—No fluid to signify within the abdomen, and no evidence of peritonitis, except a few old adhesions. *No part of the intestine lay in front of the renal tumour:* colon adherent to its lower edge. Vena cava beneath the liver occupied by a large laminated thrombus, terminating above in a blunt cone. Right renal vein likewise filled with a soft thrombus; left renal vein free from clot. Liver and left kidney amyloid. Double ureter on left side. Bladder healthy. Thoracic viscera healthy, except for a mass of caseous glands behind bifurcation of trachea. No vestige of healthy renal tissue could be made out in the tumour, which was enveloped in a loose capsule of connective tissue. R. ureter pervious, not dilated. Pelvis of kidney filled with a firm, fibrinous plug. R. adrenal loosely attached to the tumour. The tumour, upon section, exhibited a mottled, patchy appearance, and was intersected by numerous fibrous bands. Under the microscope it proved to be a spindle-celled sarcoma.

The PRESIDENT said the case was remarkable for its rarity, many of the profession having passed through a long life without seeing more than one or two.

Dr. HENRY KENNEDY said he had never seen it in the adult, though he had seen six cases in children. Walsh, in his celebrated book, mentioned the fact of strumous disease co-existing with malignant disease. The strumous glands most probably appeared early in life, while the malignant disease was of subsequent growth. It was scarcely compatible that the two should grow together. It was also questionable whether hæmorrhage was a direct symptom of the disease. In the case of the children he had seen it was not present.

Dr. JAMES LITTLE said he never saw a case of cancer of the kidney, but he emphasised the fact mentioned by Dr. Smith of the great importance of noticing the condition of the colon in the diagnosis of renal tumours.

Dr. FINNY having seen Dr. Smith's case, confirmed what he had stated about the position of the ascending or transverse colon; but the peculiarity here was that it did not pass in front, but below the tumour. That was the difficulty. A short time ago he had a patient in hospital in whom it was easy to define the descending colon passing over the tumour, and his colleagues concurred with him that the

tumour was a renal one. Another point in Dr. Smith's case was that the handling of the tumour gave little pain, and it seemed to be only troublesome from its great size and position. There was a distinct rounding of the kidney in the early stage. Afterwards that growth evidently became involved in the general mass, resulting in one continuous large tumour. The illustration of the presence of mucin, and the peculiar objects passing down from the urethra, gave the case additional interest.

Dr. WALTER G. SMITH in reply, said he was almost disposed to envy Dr. Kennedy's exceptional experience of the disease. He was not aware that anybody in Dublin had seen so many cases of the disease, even in the early period of life, whereas it was well known one-third occurred in the first decennium of life and the remaining two-thirds in later life, the period from ten to twenty-five having almost an immunity from malignant disease of the prostate or kidney. He did not think that Dr. Little or anyone could lay too much stress on the importance and generality of the rule of the existence of intestine in front of the tumour. It was a singular circumstance, but by no means peculiar to his case, that there was a comparative absence or slight degree of pain, the disease being a slow, infiltrating affection.

On the motion of Dr. DUFFEX, seconded by Dr. M'SWINEY the remaining papers were referred to the Council for publication, and

The Section adjourned.

## Sanitary Department.

### RECENT OUTBREAKS OF ENTERIC FEVER (*continued*).

WE have received from an American source an interesting account of an outbreak of enteric fever which took place this spring at Plymouth, in Pennsylvania. Dr. French, Surgeon to the Philadelphia Police, and Dr. Shakespeare, Pathologist to the Philadelphia Hospital, were, on May 7th, commissioned by the Mayor of Philadelphia to proceed to the scene of the epidemic, and make full investigation thereupon. The following is the substance of their report:—Plymouth is a considerable town, of 8,000 inhabitants, on the left bank of the Susquehanna river, two miles and a-half below the city of Wilkesbarre, which contains 30,000 people. Most of its townspeople are miners, who dwell in two streets parallel to the river, and several cross streets connecting these. From one-third to one-half of the sewage of Wilkesbarre reaches the Susquehanna, and the remainder is retained in cesspools. The river outlet of the sewage of this town is three miles below Plymouth, but the river between Wilkesbarre and Plymouth receives the refuse of abattoirs belonging to the former place, and also the sewage of Kingston, a small town opposite Wilkesbarre. The water supply of Plymouth is mostly from mountain streams above the town. The water proceeding from these streams is dammed at four points, and led to four reservoirs containing from 250,000 to 5 million gallons. From these it is led to the town by the means of the Plymouth Water Company's mains, which supply the whole town but "Welsh Hill." The water main proceeding from the lowest reservoir separates into two chief divisions, the "Back Street" and the "Main Street" mains. During drought, river water is pumped by the Company into the latter. The people on "Welsh Hill" depend chiefly on wells, but also use the Susquehanna water, which is pumped to them by a coal company; they do not use mountain water at all. It was calculated that of a total of 400,000 gallons of river water pumped by the coal company, 150,000 were used by the inhabitants of this part of Plymouth. The pumping station of the water company is two miles below the point where the lower Wilkesbarre sewer empties itself. Just before the

outbreak, the supply of mountain water became inadequate owing to the frozen state of the streams, and the reckless tapping of the mains by the Plymouth people. From March 20th to March 26th, water was continuously pumped from the river to the "Main Street" main. But so much was pumped that it also reached the "Back Street" main, and through it the lowest reservoir. On proceeding to make their inquiry, Drs. French and Shakespeare found that Plymouth had suffered endemically from enteric fever each autumn to some extent, but that the present outbreak was of marked suddenness, beginning on April 10th, and involving between that date and April 20th, no less than 500 victims. Altogether, the epidemic attacked 1,200 persons, an attack-rate of 150 per 1,000 living at all ages. The disease was at first variously thought to be malarial fever, typho-malarial fever, and the like, but all doubt was set at rest by an autopsy made by the two Philadelphia doctors, who demonstrated to the profession at Plymouth the characteristic intestinal lesions of enteric fever. On seeking the cause of the outbreak, the sewage-polluted Susquehanna water seemed, *prima facie*, to be the guilty agent; but this hypothesis was negatived by the fact that the majority of the sufferers used water which was least contaminated by this source, and the minority drank water which was subjected to maximum pollution by it. It was found, too, that amongst the 800 people living at "Welsh Hill" all of whom drank Susquehanna water taken from it half a mile nearer the Wilkesbarre sewer outlets than the pumping station, only nine suffered. Indeed, in the town, excluding "Welsh Hill," 10 per cent. of the population were attacked, whereas at "Welsh Hill" itself only about '08 per cent. of the population were taken ill with the disease. So, another channel of infection was sought out. A committee of local physicians at Plymouth reported the circumstance of a case of enteric fever existing at a house less than 80 feet from the mountain stream running between the last two reservoirs. On inquiry, the commissioners found that such a case had existed during the three months preceding the April outbreak at Plymouth; that the nurses in attendance threw the dejecta on the ground near the mountain brook at night, and during the day into a privy which communicated directly with this stream by means of the porous subsoil in which it was placed. During the first three months of the year the ground was frozen and snow-covered. At the end of March a thaw set in, and on April 2nd a heavy fall of rain took place. Hence, the accumulation of specific excrementitious matter was swept into the stream at this time, and the velocity of the current and rocky nature of its bed both hastened its extension and prevented its deposition. And that this sudden entrance into the general water supply, at a time when it was unduly diminished, of specific matter, was the cause of the outbreak in Plymouth there seems to be little doubt. Drs. French and Shakespeare, in conclusion, recommended (1) that houses near the reservoirs should be purchased by the sanitary authorities, and similar ones not allowed to exist; (2) the removal of decaying wood from the sides of the ravine through which the mountain stream flows; (3) discontinuance of the Susquehanna water as a source of supply; (4) tapping and cleaning of the blind ends of the water mains; (5) abolition, as far as possible, of surface wells liable to be polluted, and thus to cause continuance of the epidemic. Particulars of the social destitution caused by the outbreak, and a brief general account of the means of refuse disposal of the town complete the report.

*Remarks.*—The above outbreak bears, as is observed by

the authors of the report, a striking similarity to the classical Lausen epidemic of 1872, and deserves therefore close study and careful record. On referring, however, to the particulars of the Lausen outbreak, this will be found to present a less complicated set of conditions than the Plymouth one. For, the circumstance that the foul Susquehanna water obtained access to the lower reservoir cannot be set aside, and this, coupled with the previous pumping a fortnight before the beginning of the outbreak, would seem to implicate the river to some extent. It would have been well if Drs. French and Shakespeare had presented some statistical comparison of the incidence of the fever on houses supplied solely from the river, on those receiving mountain water only, and those drawing from a mixture of these supplies. Reconciliation of the facts may perhaps be effected by supposing that the excrementitious matter swept down from the house between the third and fourth reservoirs found in the foulness of the water in the fourth reservoir a condition suitable for the life and development of the specific germs which it contained.

### THE VOLUNTEER MEDICAL STAFF CORPS.

#### THE CAMP, ALDERSHOT.

THIS Corps has just spent a week under canvas at Aldershot, and probably no corps of Volunteers ever received so hearty a welcome on their arrival, such kindly attention during their stay, or such a truly friendly farewell as was given to the Medical Staff Corps. For some time it had been known in Aldershot that the Corps composed mainly of students from the London Schools of Medicine was coming down for a course of instruction, and on their arrival they were met by large numbers of the regulars, especially those connected with the Medical Staff Corps stationed at Aldershot. On their arrival the officers were made honorary members of the Medical Staff mess, and the sergeants were in the evening entertained in a most sumptuous manner by the sergeants of the regulars. Each morning there was a parade at 6.15, for one hour battalion drill, the Medical Staff Corps and the Volunteer Medical Staff Corps working together under Surgeon-Major Ray, and a second parade at 8.30, for a field day or for special work as bearer companies. One day was devoted to practising the duties of the corps on a battle-field, under the superintendence of Surgeon Miller. Some seventy men were sent out as wounded, ticketed with the nature of the wound. These men covered a space of ground more than a mile square, and like wounded would naturally do, secreted themselves behind the gorse and hillocks in the shade and out of sight of the enemy, and therefore out of sight of the bearers. The Volunteer bearers were sent out to search for the wounded, to dress their wounds, and to bring them in to the collecting station, where the ambulance waggons were in waiting. They performed their work uncommonly well, and did not fail to recover all the seventy who had been sent out in the early morning. As they brought the wounded up to the collecting station they loaded them into the waggons to be taken off to the field hospital situated in a well selected spot in the shade of a wood and out of range of cannon-fire. During the practice we noticed a curious anomaly: the officers commanding com-

panies in the Volunteer Medical Staff Corps rank in the Army List as Lieutenant-Colonels and as Majors having been transferred from different regiments; but in this Corps they have had granted to them only the rank of Captain, and therefore they were not mounted. Consequently, from the time the bearer detachments received the order to search for wounded they were never seen again by the Commander of the company until they arrived with the wounded at the collecting station, and had there been a retreat along the line, no order could have been issued to the Commanders of sections, and no communication whatever held with the bearer detachments. It is clear that the Commanders of companies must be mounted. They are mounted in the regulars, and the work and the requirements of the Volunteers must in no way differ from that of the regulars. Why in the Volunteers the Commander of a bearer company should receive the rank of Captain only, when in the regulars it is necessary that the same officer should be a Surgeon-Major, we are at a loss to understand. The War Office might just as reasonably issue an order that in future the Commanders of Volunteer battalions shall rank as Majors only instead of Lieutenant-Colonels. There is another suggestion we should make to the Volunteer Medical Staff Corps, and that is that they should apply to the War Office for permission to have a band. We are aware that Departments have not bands, and that the Medical Staff Corps have no band, but that is no reason why the Volunteer Medical Staff Corps should be refused. Among the students are a great many excellent musicians, and there would be no difficulty in getting together a volunteer band, the cost of which would be simply the cost of the instruments and an instructor. The Corps will doubtless soon have enrolled the full number allowed; and for smartness in movement of a body of men on the march a band is a *sine qua non*. The Corps has benefited greatly by its stay in Aldershot, and certainly the officers stationed at Aldershot have, regardless of personal time, trouble, and inconvenience, devoted themselves to the instruction and comfort of the Corps. Surgeon-General Hendley, the P.M.O. of the district, received the officers at lunch, and presided on the guest night at the mess, on which occasion the Director-General was present. Surgeon-Major Ray gave them a battalion drill every morning. Surgeon-Instructor Miller was indefatigable in his endeavours to assist them on field days in the formation of field hospitals, collecting stations, bearer work, &c. Surgeon Rutledge, as chairman of the mess, studied that they should not be wanting for the good things of this life. Surgeon Grier watched over them throughout their visit to see that nothing was wanting. Quartermaster Adjutant Buckley devoted himself to their comfort, and every member of the Staff, without exception, sought to render his visit a pleasant one. On Saturday, the 15th, before leaving Aldershot, Surgeon Miller gave practical instruction at the railway station on entraining the wounded at 6 a.m., and at 10, after striking the tents, athletic sports were held—tug of war, races, tent pitching, &c., for prizes, between the regulars and the Volunteers. At 12.30 the Volunteer Medical Staff Corps marched off, amidst the cheers of the regulars, large numbers of whom followed and accom-

panied the Corps as far as the station. At the station they were met by the Surgeon-General, and by every member of the instructing staff, who bade them farewell as the train left the station.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, AUGUST 19, 1885.

#### THE MEDICAL PROFESSION AND LUNACY CERTIFICATES.

The crusade against medical men grows apace. The profession has again proved vulnerable in point of law, if not in point of equity and justice. The number of victims sacrificed to gratify a public craze, private spleen, or individual rapacity is increasing at a rate so alarming as to justify an appeal to the profession at large, in the interest, not only of its units, but its own integrity. When the good name of a medical man has become so open to reproach, when his home and all he holds dear are “desecrated and displeasur’d” by greed and calumny, it is time and more than time to ask, where is our unity, our power of resistance and our “shoulder to shoulder”? No one can afford to despise the warnings rung out by recent events. The day of law suits and their attendant expenses, troubles and anxieties is possible at any moment to any of us, and no assurance of innocence should lull us into a feeling of security. While lawyers can profit, it is not likely that they will be thin-skinned

regarding the misery they may entail on medical men. Given the sinews of war, and the most absurd actions are possible. The conclusion can not be evaded, that either the medical profession must consolidate more effectively or it must go to the wall. The utter flabbiness of the British Medical Association as a weapon of self-defence is nowhere more evident than in its helplessness when any member falls into trouble. There is lacking that universal brotherhood and community of sympathy between all sections of the medical fraternity, which throbs responsively through all its branches to the pain or misfortune of an individual unit however humble or obscure. What has the British Medical Association done in the defence of medical men? Smaller and poorer corporations protect their members, with an energy and success that might well make us ashamed of ourselves. The case of *Neave v. Hatherly* and *Gardiner* in the Queen's Bench Division, a few days ago, will stir up sympathy for Mr. Hatherly; but it ought to bring out something more tangible and practical than sympathy. Sympathy is cheap; something more palpable is wanted. The plaintiff, Miss Neave, is in her fiftieth year, and four years ago was certified insane by Mr. Hatherly, the family medical attendant, and Dr. Gardiner since deceased. Mr. Hatherly had no knowledge of the place of treatment determined on, nor was he the instigator of the proceedings. He was asked to examine and certify, and simply confined himself to these duties. Miss Neave's leading delusion was that she was being victimised by Jesuits whose evil counsels actuated her household, that the servants were tools of the Jesuits, and her brother was guilty of improper intercourse with the nurse who was, under Jesuitical influence, trying to poison his child. Inspired by these and kindred delusions she waged war day and night against the household, and had become quite intolerable when recourse to asylum treatment was resolved upon. Lord Coleridge's charge to the jury was characterised by a more accurate estimate of the evidence than might have been expected, but whether it was too learned and involved for the grasp of an average jury intellect, we will not venture to say, contenting ourselves with the fact that the jury failed to arrive at a verdict consistent with the charge and the evidence. It is no compliment to Mr. Hatherly's professional sagacity that the jury found the plaintiff sane at the time of her committal, nor will it relieve his mind to know that they did not consider him guilty of culpable negligence in signing the certificate. If the signing of medical certificates is to be regulated by such conclusions as we have indicated, the result foreshadowed in the speech of Lord Coleridge is not far distant. In other words all respectable medical men will soon cease to grant certificates. We question if a clearer case has ever come before a court of justice, and the onus of refusal to sign certificates will ere long rest with the general public which is represented by jurymen of such conspicuous mental obliquity. Two similar cases are now in the law courts, but being *sub judice* one cannot here comment on them; in the meantime, the sooner the medical profession stands on its own defence the better, for it is in danger of being swept aside by every adverse wind that blows, and a careful study of the interesting and suggestive paper by Dr. Turnbull which appears in another column, will do something towards the attain-

ment of a clearer and more enlightened view of this much-vexed question.

#### TRAM CAR SLAVERY.

MANY of the daily newspapers have recently contained letters complaining of the long hours during which conductors in the service of tramway companies are compelled to remain on duty, and the revelations made on the part of the employes are such as should awaken the utmost indignation. In many cases it is shown that men are required to work for as many as sixteen hours per day, and this not merely during six days, but on the seventh also, and without any save the most exceptional opportunities for obtaining the Sunday of relaxation to which every labourer is supposed to look forward as means of securing needed additional rest. That such a condition of things should be possible in a country where it is a special care of the State to look after the health of all classes of the community, and to regulate the conditions under which various occupations are carried on, is a startling reality; and tardy though the effort to remedy it is, we cannot but feel satisfaction at the commencement of an agitation intended to remove so serious an obstacle to general progress. Great as is the capacity of the human frame for enduring extensive strains upon its strength, such a demand as that to which tram car conductors are subjected by the terms of their engagements, is one that can be supported for only a limited time without such injury to health as must inevitably lead to the production of unhealthy children, and in this way to the weakening of the coming generation. It is sufficiently obvious that this danger is a practical one, and that any occupation which interferes with the bodily health of its followers by unduly straining their physical powers, has a necessary tendency towards degeneration in a large number of working men; added to which the wages earned by such lengthened toil and exposure are often barely sufficient to procure the necessaries of life for the families dependent on the earnings of the father so occupied. It has been suggested that the hours shall be reduced to fourteen, but this change will not be at all an adequate remedy for the evil that is complained of, not even when the additional gain of every other Sunday as a day of rest is granted with it. Every man requires at least one day per week on which he shall be relieved from the pursuit of his habitual labour, and which shall be for him a period of rest and recreation. Moreover, the most willing spirit is not able to work continuously more than twelve hours *per diem*, without being slowly undermined in health, and hastening the period of natural decay, for by so doing he deprives the organs of his body of the repose that is essential to the due performance of their several functions as is the food on which they depend for nutrition.

From the employer's point of view, of course, such considerations as these are out of place. They look mainly to the profit to be gained out of the sacrifices made in their interests; and, unfortunately, they are to all appearances justified in driving harsh bargains with their men by the ease with which they are enabled to fill all vacancies from the crowd of unemployed applicants.

But though on this account it is not to be expected that the men themselves will insist upon a radical change in the regulations under which they work, it is not, therefore, the less incumbent on others to obtain for them the needed redress; and on public grounds of expediency an early reform of this description should be insisted on by those who are able to recognise and appreciate the ultimate effect of the burden under which these men labour. A very considerable number of men are concerned in this connection; as a body they cannot help themselves, but they may be trusted, when the means of doing so is presented to them, to promote their own emancipation as far as possible. Efforts to this end have been proposed, and, like all similar attempts, they will require to be long sustained and powerfully assisted before they can be completely successful. The cause, however, is one that well deserves encouragement and support; the benefits to be conferred will have more than an immediate result, and will tend with other measures in progress to assist in the moral and physical elevation of the working classes, for whom so much is now being done.

#### THE COMPENSATION OF IRISH WORKHOUSE OFFICERS FOR ABOLITION OF THEIR OFFICE.

We very much regret to state that the saving clause which the Irish Medical Association caused to be inserted in the Poor-law Officers (Ireland) Bill during its passage through the House of Lords has been, on reconsideration of the Bill in the Commons, so altered as to deprive the clause of most of its value. We explained last week that, according to pre-existing law, the workhouse officers were secure of their salaries whether they were disestablished or not, but that this security was very seriously imperilled by this Bill, which left the compensation for loss of office discretionary with the guardians.

To make it clear that this discretion should not touch the pre-existing rights of officers, the Irish Medical Association promoted the saving clause, but when the amendment went back to the Commons, Mr. Sexton and Mr. Healy insisted on the word "salary" being struck out, and the Attorney-General for Ireland weakly gave way, as, indeed, he would have given way to anything whatever the same party might ask.

The Bill, with this omission, is now law, and the best hope we can hold out to the disestablished officers is that it does not positively repeal their pre-existing rights, and that those rights may yet be established before the law courts if the guardians, as may be expected, refuse to do justice to their officers.

It is appropriate, in view of the coming General Election, that we should remind the Poor-law officers of Ireland that they owe no allegiance to Mr. Sexton's party. That party it was which, year after year, has prevented the House of Commons from according to Irish Poor-law officers the bare justice of a superannuation in their declining years of meritorious service. That party it was which, without pity, or even decency, drove out the medical officers to starve or beg when every other political party was willing to recognise their claims upon the

public. Every attempt to place the Irish Poor-law medical officer in a better position has been persistently opposed by that party, and its last act has been to do its utmost to deprive that officer of compensation when his office is taken away from him. If the five thousand Poor-law officers in Ireland are foolish enough not to know their enemies from their friends they have only themselves to thank for being put under foot by Mr. Sexton and his followers. It is our political creed that a doctor, as he cannot exercise any material influence in general politics, should vote for his own profession and for its interests, and should make his mark in his ballot-paper against every candidate, be he Tory, Whig, Radical, Parnellite, Democrat, Royalist, or Fenian, who has shown his enmity to the cause.

Messrs. Sexton and Healy are not, however, solely to blame for seeking to deprive Irish Poor-law officers of compensation for abolition of office, for we have learned that their action in this matter has been prompted from a direction which no one could expect. We have ascertained with astonishment and regret that one of the Secretaries of the Poor-law Officers' (non-medical) Association, without consulting his executive, in defiance of the opinion of his colleague, and preferring his own interpretation of the law to that of the Solicitor-General and Mr. Purcell, Q.C., wrote surreptitiously to Mr. Sexton, M.P., asking him to oppose the action taken by the Irish Medical Association on behalf of the Poor-law officers. If this gentleman had pleased to elect himself to be the Irish Poor-law Officers' Association, and had acted on their behalf openly and straightforwardly, he might be left to settle the responsibility for his so doing with the executive of that Association (if there be any such), but the transaction is made worse by the fact that all the information which he possessed, and upon which he acted in his negotiation with Mr. Sexton, M.P., was derived from a friendly and confidential communication with the delegate who acted for the Irish Medical Association.

Possibly this Secretary will be able to satisfy the Executive whom he has assumed to represent; possibly he may think it matters little that he has succeeded in bringing his Association into antagonism with an organisation with which it has hitherto worked in amity. We hardly think, however, that, on looking back upon the transaction, he will feel much satisfaction in the recollection that his secret plot with Mr. Sexton has gone far to deprive the Poor-law officers of Ireland of their security of tenure and of compensation for loss of office. Such a result is not a thing to be proud of, and as for this gentleman's enunciation of the law, we really must be excused if we elect to abide by the opinion of the Solicitor-General and Mr. Purcell, Q.C.

AN American journal states, that more than three thousand pounds weight of arsenic was sent into one valley in California in one week for the destruction of grasshoppers.

A FATAL case of poisoning, supposed to have resulted from the substitution of strychnia for monobromated camphor in dispensing some pills, is reported from New York.

## Notes on Current Topics.

### Vaccination Certificates.

A QUESTION was recently raised at the Birmingham Assizes which opens up considerations that do not appear to have been contemplated by writers of the comments already made upon it, but which are of sufficient importance to merit some attention. It arose in connection with the signing of a vaccination certificate by a duly-qualified public vaccinator, who had affixed his signature to the document without having himself performed the operation, this being in reality done by his unqualified assistant. In the end the judge acquitted the accused, on the ground of unintentional offence; and this result is in every way satisfactory. What we wish to point out, however, is that under the Act relating to vaccination as it now stands, there is not a single public vaccinator in the country who is not constantly subjecting himself to the risk of such a prosecution as the Birmingham surgeon referred to has just undergone. Such officers, by virtue of their position, are permitted to give instruction in vaccination to medical students, and the latter are required to have *themselves* vaccinated a certain number of children prior to receiving the certificate of proficiency required by various examining boards. Consequently, the public vaccinator returns a number of signed certificates of successful vaccination in which the operation has been done by another than himself, and that one an unqualified operator. The difficulties in connection with this question are similar to and on a par with those which arise when the death of a child occurs from injuries received during labour conducted by students prior to qualification; and in each case it seems that some special provision to meet it should be inserted in the Acts under which they are included. So long as medical education is of the practical nature it is at present, so long must practitioners run the risk of vexatious prosecution under existing Acts of Parliament; and these latter should be so modified as to prevent unpleasant surprises.

### Anatomy in American Schools of Medicine.

THE *Boston Medical and Surgical Journal* for July 30 contains an article from the pen of Dr. G. H. Monks which contrasts the modes of teaching anatomy in England and America very much in favour of that pursued in this country. The principal feature which appears to have excited Dr. Monk's admiration is the eminently practical nature of the instruction given in British schools, and the practice adopted here of applying the details of regional anatomy in connection with clinical teaching. In America the student is not encouraged to maintain an intimate acquaintance with this subject subsequently to the conclusion of the examination in it; nor does this test include anything equivalent to those "dissection questions" usual in the examinations here, and which effectually prove, by the way in which they are answered, to what extent the candidate's knowledge has been acquired practically. Speaking of America, Dr. Monk writes: "There is in our system only one examination as a rule, which may be written or oral, seldom both, and never very practical. This examination usually comes at

the end of the first year, occasionally of the second. The questions are not generally so selected as to draw out the real practical knowledge of the student. A minimum of fifty per cent. is required to pass. It would be quite possible for most students to get this fifty per cent. by a fair knowledge of the text-book alone. I know of one student in one of our best schools who got a mark of ninety-eight per cent. without ever having seen the inside of the dissecting-room. *Dissecting* itself is not often made a prominent feature. It occasionally happens that a student has no opportunity to dissect until the anatomical examination is over, in which case the stimulus to do good work is wanting. But there is no requirement, and often no encouragement, to dissect with the aid of some good manual." The writer of these remarks, which must be strange indeed in the ears of English students, further reflects on the absence of all aids to study, such as are afforded by preparations, models, diagrams, and plates, in American schools. Such museums as contain them are open but two or three hours in each week, and cannot therefore be esteemed of use as educational forces. Of the museum aids to teaching in this country Dr. Monks speaks in terms of the highest praise.

### Death from Hydrophobia.

A LITTLE girl, seven years of age, died last week in St. Thomas's Hospital, from hydrophobia, a verdict to this effect being returned at the coroner's inquest held on the body in accordance with the evidence of the house-physician to the case. The deceased was bitten on the nose by a black retriever dog while playing in a public park at Brentford on March 28th last. The wound thus caused was treated by a local surgeon, and the child had apparently quite recovered from its effects. On the 6th inst., however, she was seized with symptoms of hydrophobia, and was soon after removed to the hospital, where she died on the following Sunday, August 9th.

### M. Jules Guérin on the Cholera Epidemic.

If the view held by M. Jules Guérin, as to the cholera epidemic in France last year should be correct, it will become a serious matter for reflection, even in this country, how far the outbreaks of the disease are not due to preventible causes originating within the limits of our own towns. According to M. Guérin the 1884 epidemic was not the consequence of importation of cholera from abroad, but was of spontaneous origin, and had been preceded by a *pre-epidemic period*, during which disseminated cases of disease occur, with a mortality no less than during the extremest stages of the malady. The conditions favouring the development of the choleraic poison are those generally found in unsanitary towns, and exist wherever filth and carelessness in removing refuse and providing for drainage and water supply combine to render a place unhealthy. The course of events at Marseilles certainly lends force to the arguments employed in this connection, and forcibly show the frightful mischief arising from a want of vigour on the part of the municipal authorities, who, notwithstanding the terrible lesson taught them last year, have not even yet carried out the improvements necessary in

the interests of the public safety. M. Guérin includes among cases of cholera those instances of diarrhoea in infants which are always numerous in periods of extraordinary heat; and having paid a visit of inspection to Marseilles and Toulon, he concludes that they are at this moment in the *pre-epidemic* period of an outbreak of cholera.

#### A New Aid to Diagnosis.

SEVERAL ingenious instruments designed to assist inspection of internal organs and cavities were exhibited at the last meeting of the French Academy of Sciences by M. Boisseau du Rocher. The chief of them included instruments for examining the stomach, the bladder, and the rectum. The principle in all is the same, and consists in adapting a small electric light to the purpose in view. The instrument has the form of a sound or tube, terminated by a lantern, in the interior of which a small incandescent lamp is fixed. Above it there is an apparatus for reducing to microscopic dimensions the image of the mucous membrane under observation: it consists of a prism surmounted at a right angle by two plano-convex lenses in apposition by their convex surfaces. At the other end of the instrument is fixed a magnifying apparatus, consisting of an objective and an eye-piece, the powers of which can be varied at pleasure.

#### Early Tapping in Ascites.

THIS subject was brought before the Berliner Medizinische Gesellschaft on the 1st ult. by Dr. Ewald, in connection with the case of a woman, aged 61, who had for a long time suffered from chronic kidney disease. When admitted into the Siechenhaus in May last she was bedridden, and unable to move about. There was then slight œdema of the lower part of the trunk and legs. In the abdomen dulness was present in both flanks, which disappeared on change of position. Præcordial dulness was not increased; cardiac impulse could not be felt; cardiac sounds normal. In both lungs there was dulness behind to the level of the fifth rib, and on the left side up to the axilla. The urine was slightly turbid, and contained a large quantity of albumen and casts. There was, therefore, moderate ascites, double-sided pleuritic effusion, and simultaneous œdema. The patient expectorated and coughed a good deal, and complained of dyspnoea. The quantity of urine was between 600 and 800 ccm. On May 19th tapping on the left side of the abdomen gave exit to clear bright fluid. On the 20th the same spot was punctured with Dieulafoy's trocar, and 1,690 ccm. of fluid was withdrawn. As soon as the fluid began to run in drops the trocar was withdrawn. Percussion now gave decided increase of resonance. On June 1st the patient's condition was satisfactory. The weight of the patient had diminished by some pounds, the dulness had cleared up in both lungs, the respiratory murmur had become sharply vesicular, but the pectoral fremitus was still absent on both sides behind; the pulse was of medium tension. Dulness was no longer present anywhere over the abdomen. The œdema was much diminished. The dyspnoea had disappeared, and there was neither expectoration nor headache. There were

much fewer cylinders in the urine, but the quantity of albumen was unaltered. Examination on June 12th revealed but little change, but the œdema of the legs had quite disappeared. The patient felt quite well, was able to go about, and was shown to the meeting. Dr. Litten then related the particulars of a case of his own in which, after tapping, the daily quantity of urine reached 1,300 ccm., whilst with digitalis it never went beyond 900 ccm. He thought, however, that in a week's time the old condition would have returned.

#### The Zenana Medical Mission.

THE Zenana Medical Mission Report for 1884 has just been issued, from which it appears that during the existence of the institution 61 pupils have availed themselves of the opportunities it affords for obtaining instruction in the elementary details of medical work. Some of the women educated by the Mission are usefully employed in India, and as there is undoubted scope for them there and elsewhere abroad, it is satisfactory to know that the institution in which they get their training is progressing favourably. It is situated at 58 St. George's Road, London, S.W.

#### Aseptic Hands.

PROFESSOR FORSTER, of Amsterdam, recently determined to ascertain how the hands could be made absolutely free of germs. His experiments showed that washing in a 2½ per cent. carbolic solution was useless, as was also the plan recommended by Billroth—viz., with sublimate and 10 per cent. solution of phenol in glycerine. Washing them, however, in aqueous solution of sublimate, 1 or 2 per 1,000, after a previous thorough washing with soap and water, sterilised them so completely that the most delicate nutrient solutions gave no subsequent trace of growth of fungi. The practical bearings of such a demonstration are sufficiently obvious without enumeration in detail.

#### Cancer of the Stomach in which Diagnosis was doubtful.

At a recent meeting of the Société Médicale des Hôpitaux, M. Dujardin-Beaumetz exhibited a stomach which was the seat of an extensive ulceration which was clearly cancerous both in appearance and in microscopical structure, but which it had been impossible to diagnose with certainty during life. The patient had been suffering for three years, and the most careful observations had been made with a view to proving the cancerous nature of his disease, but in vain. Examination of the urine by Rommalaère's method gave from 15 to 25 grammes of urea, and the state of the gastric secretion also gave results negating the suggestion of cancer. Notwithstanding these conditions, however, the patient was clearly suffering from a cachexia, and there was frequent vomiting of a black material highly suggestive of malignant growth; but no signs of tumour were to be found, and this fact, coupled with the length of time during which the symptoms had persisted, seemed to overthrow the theory of cancer. The patient, after twice recovering from pneumonia, ultimately died from exhaustion produced by intractable diarrhoea, and *post mortem* the condition of stomach already described was found.

### The Sanitary Condition of Windsor.

OUR contemporary the *Lancet* having published, in its current issue, a most damaging account of the sanitary condition of the Royal borough of Windsor, we have felt it to be our duty to make direct inquiries concerning the accuracy of the report, and we have no hesitation in saying, as the result of such investigation, that the *Lancet* has either been most outrageously gulled or is unpardonably careless in the matter. Certain minor improvements are undoubtedly desirable in the sanitary arrangements of some of the poorer residences in Windsor; but not more so than is the case in every important town in the kingdom; and it is quite clear, from the recent action of the borough authorities, that they are keenly alive to their duties in this respect. The most crushing reply to the *Lancet's* unfounded strictures, however, is to be found in the mortality returns of Windsor, which show that the mean death-rate of its population for the last two years does not exceed 13.4 per 1,000, while the deaths from zymotic diseases have been only one per 1,000. It is impossible that these unusually favourable returns could be made under conditions such as the *Lancet* has described, and we cannot but express surprise that any medical authority should have been misled into making the sweeping statements indulged in by our contemporary without first being assured of the accuracy of the information on which they are based. So far as the health of Windsor is concerned, we have no fears that it will suffer more severely than other towns of like size in case of an epidemic invasion; but at the same time we would urge upon the authorities responsible for the well-being of its inhabitants that no steps should be omitted which well tend to remove any possible source of danger. No place is so situated as to justify the slightest neglect in this connection, and we feel sure that at Windsor there is an active desire to render the town as sanitariously perfect as it can be, enjoying as it does the services of a medical officer of health who is especially fitted for the duties he has to perform.

### Arsenic among the Ancients.

AMONG the mineral poisons known to and used by the people of ancient India we find that arsenic was enumerated; thus Susrutu, whose works are referred to B.C. 1400, makes mention of the white oxide, called at that time *phendshma-bhasma*, and *admakā*, and the yellow sulphuret, called *haritala*. There is every reason to believe that the same mineral in one or other of its forms was used in that country, and at that distant period as a prophylactic against malaria, and that when about A.D. 730 the Buddhist physician Weiku found his way thence to China he introduced that drug into the latter empire. There appears, indeed, to be some grounds for the belief that previous to the arrival of the Buddhists, arsenic was used in China, both as a prophylactic against periodic fevers and as a remedy in their treatment. The manner of employing the drug appears, however, to have been peculiar; thus, it is recorded that "arsenic and other medicines were carried in a belt, branches of the peach tree hung up in the house, talismans and charms of various kinds made use of, while, at the same time, by means of music of gongs and drums, and fireworks,

demons may be driven off." The *Pent'sao* or "Chinese Herbal," the date of which is referred to the period A.D. 1370 to A.D. 1650, contains instructions in regard to the use of sublimed arsenic (*Pi-shih*) in cases of ague. The process of sublimation is supposed to develop the poison of the mineral.

At the present day, at Wenchow, orpiment and king's yellow are used as prophylactics against malarious and *demoniacal* influences, infinitesimal doses being taken with cinnabar, in a little liquor, on the fifth day of the fifth moon—Dragon festival. In the case of children the drug is smeared on the forehead. Elsewhere in China arsenic *smoking*, by means of a pipe, is used as a remedy for asthma. None of these are sold in shops in China without evidence and witnesses to the propriety of the sale. The punishment of death by decapitation is inflicted upon both the seller and the buyer if fatal effects result. If not fatal they are both strangled. If the druggist ignorantly or carelessly sells the poison he receives eighty blows.

In Styria the workmen engaged in arsenic mines take arsenic as a protective against effects which would otherwise occur to them from inhaling the fumes from the furnaces in which the mineral is sublimed. One of these men has consumed above six grains of white arsenic, a quantity enough to poison three persons, without suffering the least inconvenience; and it was stated that he was accustomed for years to consume similar quantities of the drug. Another man took more than four grains of the yellow arsenic, that is, of orpiment, and he, too, had done so for years. Both these men were in robust health. It is said that the Styrians consume large quantities of butter, as well as other food rich in fats, and that the oily matters, forming a kind of soap with the arsenic, the latter is thus prevented from producing its ordinary effects upon the body. This may be so, although by no means necessarily. Having once secured a series of facts, a theory wherewith to explain them may be easily and readily presented.

MR. LAWSON TAIT has been appointed Consulting Surgeon to the Samaritan Hospital for Women at Nottingham.

THE will of Sir William Muir, K.C.B., M.D., late Director-General of the Army Medical Department, has been proved; the personal estate amounts to £8,000.

THE most reliable statistics go to prove that up to the present time the number of persons attacked by the cholera in Spain is about 150,000, of whom nearly one-third have succumbed.

THE lucrative appointment of Chief Surgeon to the Metropolitan Police having become vacant by the resignation of Mr. Timothy Holmes, F.R.C.S., Mr. MacKellar, of St. Thomas's Hospital, has been elected thereto.

WE learn from the *Temperance Banner* that a movement has been set on foot to establish a temperance hospital in Dublin. Two satisfactory conferences have already been held. The matter is now in the hands of a provisional committee.

THE decoration of the Royal Red Cross has, the *Gazette* states, been conferred by the Queen upon the undermentioned Princesses, in recognition of the services rendered by their Royal Highnesses to the Aid Society for the Sick and Wounded Soldiers and Sailors, namely, Her Royal Highness the Princess Louise, Marchioness of Lorne; Her Royal Highness the Duchess of Albany; and Her Royal Highness the Princess Frederica of Hanover, Baroness Von Pawel Rammingen.

We notice with interest that Dr. Beaney, of Melbourne, whose visit to Dublin some years ago, as well as the subsequent proceedings in Melbourne, and his candidature for the Fellowship of the Irish Academy of Medicine, were prominently noticed in the *Medical Press*, arrived in Dublin last week. Dr. Beaney has, since his last visit to Ireland, acquired the distinction of Membership of the Victorian Parliament, and we, therefore, salute him as "the Honourable James George Beaney, M.P."

### Correspondence.

#### CONDUCT OF THE COUNCIL AT THE BRITISH MEDICAL ASSOCIATION, CARDIFF.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Referring to your observations on page 152 as to the report in the *British Medical Journal* of the proceedings of the General Meeting of the Association at Cardiff, I beg to state that those remarks appear to be made from an inaccurate knowledge of the facts, which are quite correctly stated in the report in the *British Medical Journal*. Dr. Jacob's motion as it stood on the paper had become out of order owing to the new circumstances under which the committee was appointed in obedience to counsel's opinion. The chairman of the Parliamentary Bills Committee in referring to the report of that committee, had suggested that Dr. Jacob's might be brought into order by modifying the wording of it, and Dr. Foster, the Chairman of the Council, sent messengers to Dr. Jacob to acquaint him. I begged of the members present to remain and afford Dr. Jacob an opportunity of bringing his motion forward.

When Dr. Jacob entered the room there was not a quorum present. He was permitted to make his statement, and every attention was shown him. After Dr. Jacob had spoken, it being evident that the matter was far too important a one to make it desirable that so small a meeting should give a hurried decision, myself, Mr. Sibley, and two or three other gentlemen retired from the room. They did this in the interest of Dr. Jacob, as they thought it was better that the matter should be left in this position open to further consideration, rather than by a direct vote taken on the proceedings. That Dr. Jacob had a majority at the meeting is totally erroneous, as on the platform and in the body of the room there were altogether about sixteen or eighteen persons who would have voted against it. Had the meeting condemned his resolution it was felt that it might be regarded as dictating to societies within the Association as to what action they should take in political canvassing. Mr. Hart had nothing whatever to do with the matter, and it is entirely due to Mr. Hart's courtesy that Dr. Jacob had the opportunity of delivering his address and putting on record his views. I may say that Mr. Hart is not a member of the Council of the Association and does not attend its meetings.

Yours truly,  
W. C. GRIGG, M.D.

27 Curzon Street, Mayfair.  
August 11, 1885.

In order that any further controversy on this matter may be unnecessary, we have submitted Dr. Griggs' letter to Dr. Jacob. The following is the reply:—

23 Ely Place, Dublin.

Sir,—I am afraid that neither the members of the

Council of the Association who counted me out, nor the Editor of the *Journal* who is responsible for the report of the meeting were friendly to me or my proposition. I fully acknowledge their right to disapprove of it, and to speak and vote against it, but certainly not to get rid of it by a questionable *ruse de guerre*, and then to publish a statement of the facts which is the reverse of true. I accept all responsibility for the accuracy of those facts as stated by you, and I can only explain Dr. Griggs' account of the matter by supposing that his attention was otherwise occupied. The truth is that before I was permitted to proceed with my argument an effort was made by one of the Council to count me out, but a quorum was found to be present. When I concluded my observations, Dr. Drysdale, Dr. Brown, and others rose to second and support my motion, but they were told by the chairman that they need not speak, because it was obvious that there would be no opposition to it. It was the Editor of the *Journal* who, then sitting amongst the Council, interposed as the question was about to be put; it was the Chairman of the Medical Reform Committee who backed him; it was the members of the Council, and they only, who left the room; and it was the Editor who, going out last, called on the Chairman to count the meeting. And after my motion had been got rid of by this manoeuvre the *British Medical Journal* capped the proceeding by publishing a statement which falsely represented that I had been obliged to whip up members to make a house for my motion, and that the meeting had *proprio motu* decided against my proposition.

I regret that the meeting should have been so small as to make possible this manoeuvre of the Council and the Editor, but I must say that I have a strong suspicion that the public business of the Association is intentionally kept over to the far end of the general meetings in order to prevent inconvenient discussions. It is not wonderful that the members of the Association, having sat out, patiently or sleepily, a dreary "Address" of an hour and a-half, should make a rush from the room the moment that politeness allows them to do so.

It is when the room has thus been emptied that the Council makes a pretence of asking the members to consider the public business of the Association, and it may therefore be easily understood that such business is *not* considered, and that the Council, who keep their seats on the platform, can and do vote anything they please without fear of criticism.

For instance, on the particular occasion of which Dr. Griggs writes, the reports of the Medical Reform Committee and the Parliamentary Bills Committee, dealing, *inter alia*, with Lunacy Law, the Sale of Patent Medicines, the Compulsory Notification of Infectious Diseases, the Grievances of the Army and Militia Surgeons, the Registration of Midwives, &c.—reports pregnant with matter oftentimes more interesting to the profession than the weary *réchauffés* which are called "Addresses," were passed through without a syllable of criticism or a moment's thought by the same meeting which, a few minutes later, the Editor and the Council counted out.

The ostensible policy to the Association upon questions of supreme importance to the profession is thus put forth, but I beg for myself emphatically to repudiate these reports as in any way expressing the opinions of the members. I doubt whether one in five of the members of any of these committees reads its report. I am quite certain that not one in fifty of the members of the Association does so, and I know by experience that, if they did, it would be hopeless for them to attempt to get a hearing at one of these far-end meetings, and that, if they insisted on being heard, no matter what they might propose, it would be peremptorily put under foot by the Council party who occupy the platform on these occasions.

I am, &c.,  
ARCHIBALD H. JACOB,  
M.D. Dub. Univ., F.R.C.S.I.

#### DR. BRADLEY'S CASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you permit me to reply very briefly to the letters which appeared in your issue of July 29th, from Mr. J. W. Martin of Sheffield, and Dr. Ewing Whittle of Liverpool? It is known to very many of Dr. Bradley's friends that I have

had somewhat unusual opportunities of exercising influence in this particular case, and I wish to remove an impression which is very widely felt and very fully expressed in those two letters, that the Lord Chief Justice and the late and present Home Secretaries were prejudiced in any way, or took but little or scant interest in the case. I wish particularly to say that there is not the slightest ground for the comments made by Mr. Martin on the Lord Chief Justice. Lord Coleridge favoured me with a very protracted interview on this case, and submitted his notes for my perusal, and I am bound to say that any judge must have conducted the case precisely as he did on the evidence which was before him. The real faults of the case lay, as I have often pointed out faults frequently do lie, in one special direction, and that is, that a prosecution of this importance should be conducted by the Crown, and not be allowed to pass before a jury on the evidence of one practitioner. The other fault lay almost in the same direction, and was to the effect that Dr. Bradley was to a very large extent answerable for his own conviction by reason of his persistent refusal to call in evidence which could and would at once have acquitted him.

I have long argued that no criminal trial should proceed upon the evidence of any one medical witness either for or against the prisoner. The best of us may be mistaken, and it is possible occasionally that prejudice may be introduced. Certainly it is the duty of any man who is unfortunate enough to be charged with such an offence to leave no stone unturned in his defence; and now it is perfectly evident that if one or two experts had been called for the defence such a conviction as was recorded against Dr. Bradley would have been absolutely impossible. It is all very well for a man to depend, as Dr. Bradley did, upon his innocence for an acquittal, but unfortunately English jurisprudence is not a game at which mere innocence and guilt are concerned; it is far more like a chess-board, at which the most skilful player is sure of a victory.

I am, Sir, yours, &c.,  
LAWSON TAIT.

Birmingham, August 6th, 1885.

#### INOCULATION AGAINST CHOLERA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—When we reflect on the facts of vaccination and inoculation in relation to small-pox—on the fact that syphilitic hard sore is prophylactic to future infection, that one attack only, on the main, is the history of measles, scarlet fever, &c., and in the facts which Pasteur has demonstrated in relation to chicken-pox, cholera, rabies, &c., it is obvious that we are nearing a great general form or law in biology and disease, viz., a law of co-ordination, or general principle, that the most complex and dangerous phenomena of disease are after-results or *débris*, whose precipitating causes are earlier and far less powerful disturbers of the system than those phenomena commonly known as the actual disease, and we see further, that small or less potent changes, produced artificially, have the power of exhausting the capacity for the more violent changes.

The same great principle of co-ordination is seen in acclimatisation, in the use of bitters and quinine by residents in Tropical Deltas; in the use of infusion of lemons in Italy, as prophylactic of fevers. The same generic form can be recognised in the facts that it is dangerous to change the habituated "mode," or to travel during cholera epidemics. During twenty years past I have been urging that "change" of environment, is enough, at certain times, to induce those vito-chemical changes in the system whose results are cholera, holding the hypothesis that in the amazingly complex and high atomic constitution, of organic tissues, periodic access of unstable equilibrium, or natural tendency to decomposition and devolution, happen; at such periodic times I am compelled to hold that "chill," "shock," a dose of salts, and many other changes, may induce vito-chemical changes in the co-relations of the tissues, cell-contents, and fundamental protoplasm, whose results at certain times are cholera. The differences between two men, one of whom in Calcutta, in May, takes a dose of salts and dies of cholera, and who keeps well, cannot be recognised by any yet known research; function alone demonstrates it. But all this points us to the infinite complexity of the vital rates, and yet more to the infinitely delicate differences and conditions

that differentiate those who do, from those who do not, pass into cholera.

When we see that mere *change* of environment may lead to those vito-chemical actions in the organism, whose results, acting on nerve centres and on fundamental protoplasm of cell contents, are what we call cholera, and when we see on how small differences of environment, the healthy vito-chemical co-relations are maintained, we may well seek to extend the method of Jenner and the method of acclimatisation.

We can never doubt but that the assafoetida, pepper, and opium pill of Indian bazaars co-ordinates the unstable composition of tissues, and saves many from passing into the further changes, whose results are cholera; so does the cholera belt and kummerbund save; it prevents "chill" and its vito-chemical results.

Can we by analogy, gather up the form of those things which prevent cholera; can we extend in scientific continuity, the method of Jenner, or the method of the Indian pill? Is it the opium, or the assafoetida, or pepper, which affords molecular conserving "energy" against the chemical changes which precipitate cholera?

I must confess to more than astonishment at Dr. Koch's view, when he says, "Their (comma-bacilli) presence is limited to the organ which is the seat of the disease—the intestine." (*B. M. J.*, 12, 3, 84, p. 568.) It does seem surprising that in so complex a phenomenon as cholera its chief seat should be held to be the intestines! I have always seen, as prominent parts of its causation, the evolution of "poisons," altered modes of co-relation of the highly atomic matters of the body, and which, as in other known "poisons," such as snake poison, strychnia, &c., have a catalytic power on the living blood, &c., and whose influence is mostly felt on certain nerves which control the heart and other organic life centres. It is true that certain definite poisons may be parts of certain groups of bacilli, just as different plants have different qualities, and poisons even, in relation to animal organic-life structures; but such is a far more remote hypothesis than that of the possible evolution of vito-chemical poisons as consequent on chill, shock, and altered habituated environment.

I have been surprised that Dr. Ferran should select intertinal *débris* as most likely to possess the potentialities of cholera-molecular vital-energy. Were I pursuing a like prophylactic practice I should seek my "vaccine" in the lymph or blood.

But have we no analogies toward other co-ordinators against those first vito-chemical changes which are followed by cholera? It seems certain that it is the first vito-chemical change against which we have to guard. The kummerbund, the bazaar pill, the non-induction of "shock," as by avoiding saline aperients in cholera seasons, in periods of recurrent unstable vital equilibrium, save. But are we not justified in extending our methods of prophylaxis by the analogies of the Indian pill, with its gums, by the instance of the oil of lemons, as in Italian fevers, by quinine, &c., &c.? We must recognise that there is a pre-cholera stage, that at certain recurrent periods the vito-chemical "modes" of healthy process are in unstable equilibrium, and that it is toward maintaining this equilibrium and preventing the evolution of cholera "poison" (hypothetical) that our efforts must be directed.

When a "chill," or "shock," or dose of Epsom salts, &c., precipitate cholera, the vito-chemical changes which have happened are beyond our present powers of analysis; but when so small a cause leads up to them, we may feel certain that as proportionately small a prophylaxis must exist.

I believe that we are on the verge of a great generalisation in pathology, by which morbid process shall be seen to be in continuity with the rates of health, and that such generalisation will have a vito-chemical base, and that it will be a universal form in the great febrile group. I know that this is highly transcendental, but it has bearing on our methods of preventing cholera, &c. It is by no means transcendental that natives of India seek to preserve their vital "energy" by wearing the kummerbund, by carefully covering over their mouth, nose, ears, &c., when walking home at evening from the day's work; by largely using salt, &c., and that they have faith in the aromatic and opium pill, as preventing cholera.

From the facts and analysis I have stated are we not fairly justified in pursuing a prophylaxis to those not yet visibly affected, when in presence of a cholera epidemic

There are analogies pointing to cholera lymph and blood "vaccination;" also for the administration—hypodermic or otherwise—of quinine, arsenic, lemon skin oil, opium, assafoetida, salt, the permanganates, &c., &c.

I know that what I have said is vague, how can it be otherwise in dealing with the subtlest domains of biology and the cosmic co-relations of living beings! Not the less, what I have said may be in true philosophical method.

Yours truly,

WILLIAM H. PEARSE, M.D.

Plymouth, August 8, 1885.

**Obituary.**

JOHN GAY FRENCH, M.D., F.R.C.S. LOND.

ON the 28th July, a well-known member of the Bengal Medical Service passed away in the person of Surgeon-Major J. G. French at the residence of his father. Dr. J. G. French was the eldest son of Dr. Allen French, of Ballygar, co. Galway, and was educated at Trinity College, Dublin, where he took the first anatomical prize in his second year, also at the Ledwich School, and at Mercer's Hospital, where he acted for a term as resident pupil. He graduated M.R.C.S. London, and L.K.Q.C.P.I. in 1861, and in the same year took first place in the Indian Medical Service, in his 21st year. On arrival in India he was gazetted to a native regiment, and served in the Butan War, and received the medal; soon after he was chosen for Civil appointment. When on furlough in 1869 he was appointed Medical Officer of Rathdrum Dispensary, which he soon resigned, to attend at the Queen's College, Galway, the session 1869-70, taking the degree of M.D., M.Ch., and F.R.C.S. London by examination. Soon after returning to Bengal he was sent by Government to investigate and report on the endemic fever then raging in Burdwan; he afterwards was first resident surgeon to the General Hospital of Calcutta, Health Officer to the port of Calcutta, Civil Surgeon of Decca, and lastly Civil Surgeon of Patna District, Principal of the Temple Medical School, Governor of Jails, Asylum, &c., which he held until the 12th of last May.

Dr. French contracted bronchitis in Manchester where he set up as consulting surgeon when on furlough in 1881, and subsequently it developed into asthma on his return to Patna, followed by nervous affections brought on by over-work. Dr. French contributed largely to the literature of India, having written many pamphlets on cholera, fever, surgical operations, and cases, as also being the Editor of the "Indian Annals of Medical Science," and the *Indian Medical Gazette* for nearly two years; he was also Examiner to the University of Calcutta.

**Medical News.**

University of London.—The following is a list of candidates who passed the recent preliminary scientific (entire examination):—

**First Division.**—George Thomas Congreve Barber, Stephen Henry Bates, Arthur Bousfield, Charles Richard Box, Arthur Norman Boycott, Herbert Calger, John Alfred Codd, William Marshall Davidson, Frances May Dickinson, Thomas Archibald Dukes, Gabriel William Stabel Farmer, James Howard Green, Elias George Hall, Richard Tanner Hewlett, George James Hill, Herbert Henry Herden, Charles McGowan Kitching, Arthur Colborne Lankester, Arnold William Warrington Lea, Randle Leigh, Joseph Johnston Macgregor, Arthur Manknell, Geoffrey Colley March, Edward Percy Paton, John Edward Platt, Hugh James Moore Playfair, Charles Henry Powers, Herbert Ramsden, John Stewart Richards, John Robertson, Henry Stephen Sandifer, Amy Sheppard, Mary Louisa Sprigg, Mary Darby Sturge, Robert Edwin Williams.

**Second Division.**—Albert Ashton, Robert Cozens Bailey, Albert Brook Batley, Ellen Margaret Tinné Berthon, Samuel Victor Johnson Brock, Frank Calder, Henry Albert Caley, David Cannan, Lionel Vernon Cargill, Richard Henry Carlisle, Blackwell Charles, Alfred Clark, William Adams Clark, John Tertius Clarke, Archie Tillyer Collum, Frank Septimus Colton, Victor Albert Louis Edward Corbould, Albert Corner, Howard Distin, Edward Miall Dobinson, Percy William Dove, Edward Robert Charles Earle, William McAdam Eccles, Percy Charles Evans, Edward Desmond Fitzgerald, Charles John Girling, John Guest Gornwall, Frank Grange, John William Geary Grant, Joseph Green, John Harvey, John Sidney Hicks, Leonard Erakine Hill, Thomas Walter Hinds, John Armistead Home, Ernest Wickham Hors, William James How, Edward Victor Hugo, Charles Imray Kirton, Henry Brunton Kitchin, Mary Adela McCulloch Knight, Harry Lambert Lack, Frederick Lewis, Thomas Lissaman, Alice McLaren, Samuel Francis Mawson, Charles Carter Mozon, Harry Augustus de Beauvoir

Nelson, Samuel Nicklin, William Nuttall, Frederick Layton Orr, Harold Burgess Osburn, Charles Reginald Palmer, Edwin Stephen Pasmore, Reginald Spencer Pearson, Eric Leonard Norman Fridmore, George Lancelot Rolleston, Henry Roscoe, Gerald Alpress Sidmons, John Herbert Sykes, Albert Edward Tebb, Benjamin Pope Viret, Wilfrid Brougham Warde, Ernest Edwin Wara, John Alfred Waring, Garibaldi Watson, Samuel Williams, Alfred Field Henry Wray, John Young.

**Honours Candidates Recommended for a Pass.**—James Macdonald Gill, Orestes Victoriano Pisanal, Thomas Frank Bickette, Joseph Watts Roberts.

Royal College of Surgeons of England.—The following are additional lists of candidates to those which appeared in our last, who, having passed the required examinations for the diploma, were admitted Members of the College on August 10th:—

Barrett, Robert Basby, L.S.A.	Hurlbutt, Spencer, L.S.A.
Bray, Percy Dean, L.S.A.	Scott, Patrick Camie.
Hughes, John D., L.R.C.P. Lond.	Waters, Avery Clough, L.S.A.

The following were admitted on August 11th:—

Godfrey, Albert Ed., L.R.C.P. Lond.	Pollard, G. R. M., L.R.C.P. Lond.
Hefferman, W. Hilton, L.S.A.	Thornton, Edward, L.S.A.
Monk, Henry G. Hawkins, L.S.A.	Wrigley, Robert, L.S.A.
Morris, H. Maackinlay, L.R.C.P. Lond.	Yeoman, Charles, L.S.A.

The following were admitted on August 12th:—

Alexander, Samuel P., M.B. Glas.	Inman, George Arthur F., I.S.A.
Bradbury, Harvey, K. L.S.A.	Reywood, John R. L., L.S.A.
Cory, Isaac Rising, L.R.C.P. Lond.	Wallinger, R. N. A., L.R.C.P. Lond.

There were 339 candidates admitted to examination, of whom 95 obtained their diplomas; 96 passed in Surgery, and when qualified in Medicine and Midwifery will be admitted Members of the College. Of these candidates, 24 were referred for three months, 115 for six months, 4 for nine months, and 5 for one year. Fifty-nine candidates, having obtained Medical qualifications and previously passed in Surgery, were also admitted Members.

**British Medical Service.**—The following is a list of surgeons on probation in the Medical Department of the British Army who were successful at the August Examinations both in London and Netley, arranged according to the number of marks gained:—

First Half session, ending June 1st, 1885.

*S. Hickson	B. E. Moleworth	C. R. Kilkelly
H. J. Fletcher	J. W. F. Long	W. H. Bean
S. H. Lindeman	C. L. Jossling	N. C. Ferguson
E. Davis	J. F. Bateson	S. R. Wills
†S. Powell	W. T. Swan	M. L. Hearne
F. W. C. Jones	J. Eulin	S. L. Deeble
J. Meek	B. L. Macleod	E. H. Hall
A. E. Morris	J. H. Curtis	W. H. Bennet
E. Cormack	G. G. Adams	J. H. Greenway
J. F. McMillan	J. M. F. Shine	R. G. Hanley
C. O'Donel	W. B. Day	W. H. Bell
W. A. Carte	D. E. Hamilton	G. Cree
A. O. Fitzgerald	†B. G. Thompson	S. G. Philson
F. D. Elderton	C. T. Blackwell	J. M. Nicolls
E. N. Sheldrake	J. E. Power	F. W. H. D. Harris.

\* Gained the Herbert Prize of £20, the Prize in Pathology, and the Prize presented by Sir Joseph Fayrer.

† Gained the Martin Memorial Gold Medal.

‡ Gained the Parkes Memorial Bronze Medal and Montefiore Second Prize.

Mr. H. J. Dyon, of H.M.'s Indian Medical Service, gained the Montefiore Medal and a Prize of 20 guineas.

Second Half-session, ending August 3rd, 1885.

J. F. McMillan	G. J. A. Tuke	T. Daly
S. G. Allen	P. de B. Skerrett	J. M. Sexton
J. S. Green	H. C. Dent	T. H. Baylor
G. H. Symes	J. F. Greig	E. E. Cree
C. A. Lane	C. Hayden	F. L. Carte
P. C. H. Gordon	H. D. Rowan	W. H. Starr
L. T. M. Nash	H. Carr	A. A. Sutton
J. H. Brannigan	H. G. Hathway	A. P. H. Griffiths
M. O'Halloran	A. L. H. Dixon	W. S. Boles
C. S. Sparkes	C. G. Woods	H. L. G. Chevers
W. H. Pinches	P. J. Nunnery	F. J. W. Stoney
H. F. Horne	B. A. Maturin	J. F. G. Burke
J. H. Daly	H. V. Dillon	H. N. Kenny.

**Notices to Correspondents.**

MR. GUBB (Bromley).—The case shall appear in our next. We hope to find space for the translation later on.

DR. LAFAR (Cashel).—Your reply to Drs. Moloney and Russell is in the printer's hands. Proof will be sent you before publication.

FEEES FOR ATTENDANCE ON MEDICAL MEN.

O'C. says: I attended the late Dr. H. for nine months previous to his death. He was a bachelor, and by his will everything he had was left

to a Mr. K. and his (Mr. K.'s) daughter. Mr. K. had for a long period appeared to exercise a strong control over the doctor. He was no relation. None of the doctor's relations were mentioned in the will. Can I, with due regard to professional etiquette, claim payment for my attendance?

[A medical practitioner is—by etiquette as well as by law—fully entitled to obtain his fees for attendance on a medical man or his family. If he refrains from doing so, he does so strictly as a concession to good fellowship, and to spare the pocket of the patient or of his family. If there be no good fellowship in the case, and if his foregoing his fees be no relief to a family legitimately dependent on the deceased, the practitioner is entirely absolved from any obligation to refrain from asking for payment. In this case it seems that our correspondent is legitimately entitled to insist on being paid.—ED.]

DR. AUGUSTUS J. H. (Westbourne).—Quite impossible to say if letter was or was not suitable, as it passed the range of possibility to decipher. The signature was with difficulty made out, but the rest had to be abandoned.

THE SECRETARY, CHELSEA HOSPITAL FOR WOMEN.—A reply shall be sent to your note at an early date.

DR. GRIFFITH (Pimlico).—No point would be gained by inserting the letter.

LIFE ASSURANCE.

T. J. G. says: I examine a life for an Insurance Company to-day. The Company write in a few days wishing for a further examination. Am I right in asking for a second fee in such a case?

[If your original examination were in any respect defective, we think you are bound to make it perfect without an additional fee. But if the necessity for re-examination arises out of some new matter not within the scope of the original retainer of your services, you should be paid a second fee.—ED.]

THE BRADLEY FUND.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I enclose a list of subscriptions promised and received towards the above fund. Will you kindly allow it to appear in the columns of your journal? I remain, Sir, yours faithfully,

Chesterfield, Aug. 12th, 1885.

Mr. F. H. Miles	..	1 1 0	Dr. J. W. Buckle	..	0 10 0
			Dr. J. S. Johnston	..	0 10 0

DR. SCHOFIELD.—It is not at all desirable to protract delay in the matter. Indeed, the sooner the business is completed, the better for all concerned. Nothing is to be gained by protracting matters as suggested.

DR. EVERARD.—Nothing yields more comfort or is more grateful to the patient under such circumstances than a warm jacket-poultice of linseed meal. There is no better preparation of opium than the one you name. It is, moreover, reliable.

MR. STOKER.—We do not remember the amount of fees. Write to the Dean, who will give you all necessary particulars.

THE SANITARY CONDITION OF WIESBADEN.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Paragraphs as to the sanitary condition of this town having appeared in some of the London papers, calculated to mislead many who might otherwise wish to visit for health or pleasure this charming watering place, I trust you will find space in your columns to insert a few lines stating what I believe to be the facts of the case.

I have been here six weeks, and during that time, even when the epidemic was reported at its height, I have heard nothing to induce me to think of running away from the place. To my knowledge, there has not been a single case of typhus fever. What fever there has been has been gastric and typhoid of a very mild character, most likely traceable to the excessive or incautious use of cold drinks and uncooked fruit during the very great heat a month ago. In the last six weeks,

in a town of nearly 60,000 inhabitants, there have been twenty-eight deaths attributable to fever. I may add that it is now almost extinct, and that no case of fever has occurred in any of the hotels or pensions. I enclose my name and address, which you are at liberty to furnish to any who wish for further information.

I am, Sir, your obedient servant,  
AUDI ALTERAM PARTEM.

Wiesbaden, July 28th, 1885.

Vacancies.

- Asylum for Idiots, Earlswood, Surrey.—Assistant Medical Officer. Salary, £150, with board, &c. Applications, with testimonials, to the Secretary, 36 King William Street, London Bridge, E.C., on or before August 22.
- Brighton.—Sussex County Hospital.—Honorary Assistant Physician. Applications, with testimonials, to the Secretary, before September 2.
- Chatham.—St Bartholomew's Hospital.—Assistant House Surgeon. Salary, £100, with board, &c. Endorsed applications to the House Committee by September 30.
- Dublin (Cork Street) Fever Hospital.—Resident Clinical Assistant. Board provided, and a gratuity of £20 presented on having served six months. (See advt.)
- Frome Union.—Medical Officer and Public Vaccinator for the Nunney District. Salary, £77, with the usual extras. Applications by August 24.
- Kent County Lunatic Asylum.—Third Assistant Medical Officer. Salary, £120 per annum, with furnished apartments, &c. Applications, with testimonials, to the Clerk to the Committee of Visitors, on or before August 25.
- Manchester.—Owens College.—Professorship of Physiology. Applications to Dr. Greenwood, Principal of the College.
- Mason Science College, Birmingham.—Demonstrator in Physiological Department. Applications on or before August 26.
- Salisbury Infirmary.—House Surgeon. Salary, £100, with board. Applications to the Secretary by August 21.
- Shipton-on-Stour Union.—Medical Officer. Salary, £58 per annum. Applications, with testimonials, to the Clerk, not later than August 23.
- Stockton-upon-Tees Hospital.—House Surgeon (non-resident) Salary, £200 per annum. Applications, with testimonials, to the Secretary, not later than August 24.
- Weston-super-Mare Hospital.—House Surgeon. Salary, £70 per annum, with board, &c. Applications, with testimonials, to the Hon. Sec., on or before September 5.

Appointments

- BEEVOR, C. E., M.D. Lond., M.R.C.P., Physician to Out-Patients to the Great Northern Central Hospital, London.
- BRUSKILL, R. D., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the Co'north District of the Sedgfield Union.
- BULLOCK, J. G. W., L.R.C.P. Ed., L.R.C.S. I., Medical Officer to the Rugby Union Workhouse and District.
- COLMER, P. S. H., M.D. Durh., L.R.C.P. Ed., L.F.P.S. Glas., re-appointed Medical Officer and Public Vaccinator for the No. 3 District of the Yeovil Union.
- DOUGLAS, A. E., M.D. St. And., F.R.C.S. I., Medical Officer to the Floating Hospital, Warrenpoint, in the Newry Union.
- HOCKER, C. P., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the South District and Workhouse, Cirencester Union.
- JOLIFFE, A. E., M.B. C.S., L.S.A. Lond., Senior House Surgeon to the Cheltenham General Hospital.
- KING, J. C., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer and Public Health Officer to Castlepollard Dispensary, Co. Westmeath.
- MACANDREW, H., M.B., C.M. Ed., Junior Assistant Medical Officer to the Falop and Montgomery Counties Asylum.
- SHIRLAW, J. L., M.B., C.M. Ed., Medical Officer for the Ferryhill District of the Sedgfield Union.
- TOMKINS, H., M.D. Q.U.I., M.R.C.S., L.S.A. Lond., Medical Officer of Health for Leicester.

Births.

- HERON.—August 10, at 73 Southwark Bridge Road, the wife of J. Heron, M.D., of a son.
- REID.—August 11, at 31 Bridge Avenue, Hammersmith, London, the wife of John Reid, M.D., of a daughter.
- SAUNDERS.—August 9, at Denburn Crail, Fifeshire, the wife of F. A. Saunders, F.R.C.S., of a daughter.
- STARTIN.—August 13, at Surbiton Hill, Surrey, the wife of Jas Startin, M.R.C.S., of a son.

Marriages.

- CHESTNUTT-CLOUGH.—August 15, at Howden, East Yorks, John Chestnutt, L.R.C.S., L.R.C.P. Ed., of Trales, to Annie Elizabeth, younger daughter of the late Thos. Clough, Esq., of Malton.
- HAMILTON-CUOLAHAN.—August 13, at St. Leonard's Church, Streatham, Rupert Hamilton, Esq., of Berkhamstead, to Marie Stewart, eldest daughter of the late Hugh Cuolahan, M.D.

Deaths.

- BECKINGSALE.—August 10, at Newport, Isle of Wight, J. Edgar Beckingsale, F.R.C.S., J.P., aged 75.
- GOODACRE.—August 14, at Wilby Rectory, Norfolk, the Rev. Francis B. Goodacre, M.D., M.B. Cantab., Rector of Wilby and Haigham.
- GRIFF.—August 4, at Bedford Street, Covent Garden, Joseph Collings Griff, F.R.C.S., aged 49.
- SMALL.—August 3, at Albano, Thomas Gerard Small, M.D., of Dublin, for many years resident in Rome, aged 82.
- TURNOUR.—June 31, at Perth, West Australia, Charles C. Turnour, M.D., late of Edinburgh, aged 33.

THE

### TREATMENT OF PLACENTA PRÆVIA. (a)

By JAMES MURPHY, B.A., M.D.,

Surgeon to the Sunderland Infirmary; Lecturer and Examiner in Botany at the University of Durham College of Medicine, Newcastle-on-Tyne.

MR. PRESIDENT AND GENTLEMEN,—When your Council paid me the very kind compliment of asking me to inaugurate the discussion in obstetrics, I ventured to suggest "The Treatment of Placenta Prævia" as a subject in which most of us can take part, and all must have an interest in; for, while it is admittedly one of the most serious complications of labour, several methods of treatment have of recent years been introduced which have greatly lessened its terrible mortality, while at the same time there is by no means an unanimity among obstetricians as to what are the best means of treating the complication, and the experience of the members of this Society who have treated cases will, I trust, help us to arrive at more definite lines of treatment than at present prevail.

The placenta, I need not remind you, is said to be prævia "when it is attached to any portion of the uterus, which is subject to distention during labour" (Lusk), and has distinctive names given to it according to its relation with the internal os; thus it is said to be:—

1. *Central or complete*.—When, after dilatation of the internal os, the placenta only can be felt.

2. *Partial or incomplete*.—When, with dilated os, there is recognisable a portion of the membranes as well as a segment of the placenta.

3. *Marginal*.—When the placenta border stretches down to, but not beyond, the internal os.

4. *Lateral*.—When the placenta, though attached to the spherical surface of the lower part of the uterus, does not reach the margin of the os.

To this latter class belong a great many of the cases of so-called accidental hæmorrhage.

(a) Read before the Northumberland and Durham Medical Society.

The placenta is never attached to the cervix, a fact that was first insisted on by Professor E. T. Taylor, and is now generally admitted, since Kuhn, who investigated the subject with Karl Braun, found that in no case was the placental portion, which occupied the cervical canal, adherent to the canal walls, but that in all post-mortem examinations the remains of the placenta prævia materna ended by a sharp border line at the os internum.

The frequency of placenta prævia is variously stated by different investigators. Johnson and Sinclair gave it at 1 in 573 (Rotunda Hospital, Dublin); Schwartz, 1 in 1,564 (among 519,328 deliveries in the Grand Duchy of Hesse); Müller, as occurring 813 times in 876,432 births, or not quite 1 in 1,000.

Lomer reports 136 cases in 6,882 births, or 1 in 50, in Schroeder's Clinic; but as this is in hospital practice, of course the percentage is too high for a general rate; but he points out that at Schroeder's Clinic and the Charité (both in Berlin) the annual number of cases is 65; and as this does not include the cases occurring in private practice, it gives the minimum of frequency in Berlin, in which the annual number of births is 46,000, so that it occurs at least once in 728 deliveries.

As regards the mortality, Churchill puts it down 1 in 3; Read, 1 in 4½; Müller at 40 per cent.; Simpson, 1 in 3, or, as he forcibly puts it, greater than that of cholera or yellow fever, and double that after the operation of lithotomy. How much the mortality has been reduced of recent years by individual operators may be judged by a comparison of the tables on next page, which are copied from Lomer's paper in the December number of the *American Journal for Obstetrics*.

In the majority of cases we have warning that the placenta is presenting from the hæmorrhages that take place towards the end of pregnancy. These were formerly supposed to be due to the cervix casting off the placenta in the act of its being taken up and expanded during the last months of pregnancy. With a few exceptions, however, most writers have abandoned this theory, for the good and sufficient reasons, first, that the cervix does not expand so early as the floodings occur, or, indeed, until very near the end of pregnancy; and, secondly, that the

placenta is never attached to the cervix. Dr. Barnes then suggested "that the floodings occurred from detachment of the placenta, arising from an excess in rate of growth of the placenta over that of the cervical zone, a structure which was not designed for placental attach-

ment, and which is not fitted to keep pace with the placenta. Hence, the placenta shoots beyond its site, and hæmorrhage results." Now, great as is my respect for Dr. Barnes, I very much doubt if hæmorrhage ever occurs from this cause. The idea that the placenta shoots beyond its site is purely hypothetical, and would apply to normally situated placenta as well; and, though I carefully looked for it, I never found atrophy or other indication of its having occurred in any of the cases that I have seen. Further, the bleeding would be more likely to occur at the circumference than at the centre, and would be placental and not uterine, which Dr. Barnes alleges not to be the case. I have no doubt that bleeding occurs from the four causes stated by Dr. Matthews Duncan, namely, either by rupture of an utero-placental vessel, or marginal utero-placental sinus, by partial separation of the placenta from accidental causes, such as a jerk or fall, or in consequence of uterine pains from miscarriage commencing, but being arrested at an early stage. But if we consider that contractions are frequently taking place in the uteri of pregnant women, and that these contractions have more or less of a shrinking effect on the normally placed placenta, and have a decidedly expanding effect on the placenta placed over the os, we readily perceive how liable an utero-placental vessel or sinus is to be opened, or even a portion of the placenta itself detached. Whatever be the cause, certain it is that such hæmorrhages occur with great frequency towards the end of pregnancy. But I have never observed that they coincided with monthly periods, as has been stated by some writers. When they occur early they generally lead to abortion, and thus indicate the proper treatment; but, failing this, hæmorrhage, occurring in the latter half of pregnancy, without apparent cause, should be regarded as in all probability the result of placenta prævia; and on examination, should the vaginal fornix be found soft and boggy, the cervix soft, thick, and patulous, with vessels that pulsate strongly, the suspicion is increased, and though Wallace (Ed. *Med. Journ.*, 1872) states that the placental bruit may be heard with startling distinctness by means of a curved wooden stethoscope, the diagnosis is only rendered positive by introducing the finger through the os and touching the placental mass.

When the diagnosis is thus established positively, or

even when we have strong presumptive evidence of its existence, how should we proceed? This is the first point to consider in the treatment of placenta prævia, and it is one which I trust the members who take part in the discussion will consider the importance of; and the question at once resolves itself into whether labour should be brought on then and there, or an endeavour made to prolong the pregnancy to its normal period. The older writers recommend the latter course, and we are told to keep the patient on a hard mattress, to apply astringents and cold to the vagina, to give cold and acidulated drinks, and exhibit opium and even ergot. But though a portion of this treatment may be all very well in not at least increasing the hæmorrhage, we must bear in mind that all this time the patient is in great and imminent danger. In spite of all these precautions, hæmorrhage may occur at any time, and must occur when labour sets in, and we cannot foresee when it may take place, or calculate in what quantity it will pour out; and it may be, and often is, so sudden and so terrible, that death occurs before assistance can be obtained, or that the patient is so exhausted that assistance, when it comes, is powerless to save life. I would impress on this Society that the horrible mortality in placenta prævia is not due so much to the impotence of our art as it is to violent hæmorrhage occurring before assistance can be obtained, or where that assistance is of a helpless doing-nothing character. Why, then, should we hesitate to bring on premature labour at once when placenta prævia is diagnosed, when by means of Barnes's bags we can safely bring on labour at any time or fix the time as easily as for an ovariectomy or lithotomy and bring a skilled assistant to help us in the operation and to share the responsibility? If this be desirable, as it is, in the case of men who make obstetrics a special study, how much more advantageous is it in the case of the immense number of practitioners who have no peculiar penchant for midwifery, but loathe and detest it, and merely regard its practice as one of the stern and unpleasant necessities of what we are pleased to call the noblest and most self-sacrificing of professions. Playfair, Lusk, Barnes, and most modern writers suggest, if they do not actually advise, this active mode of procedure. But it may be objected to on the grounds that it lessens the chances of the child's life; let us see how far this holds good—Müller finds, as the result of his extensive and most important investigations, published in Stuttgart in 1877, that the hæmorrhage occurs in greatest frequency from the twenty-eighth to the thirty-sixth week in complete presentation, and in the incomplete varieties most frequently after the thirty-second week, and in no instance out of 912 cases that he has collected has death occurred before the seventh month. Now, though a seven months' child has not a very great chance of living (except it be a first baby, which it is notorious do excellently well), still its chances of life are not increased by the frequent floodings that are likely to occur before its birth, which will in all probability be premature, and it appears to me stands as good or a better chance by being delivered then, than by allowing pregnancy to continue, for let us consider what is the mortality of children in placenta prævia according to different authors:—

Schwartz . . . . .	76 per cent.
Hecker . . . . .	67 per cent.
Barnes . . . . .	63 per cent.
Müller . . . . .	64 per cent. (average of 2,360 cases.)
Fritsch . . . . .	60 per cent.
Spiegelberg .. . . .	50 per cent.
Braun . . . . .	50 per cent.

Now these numbers refer mostly to the question whether the child was born with life, not whether it remained alive, which is a very different matter. For example: Behm had 78 per cent. born with life, but of these only 29 per cent. lived, so that instead of having 78 per cent. of children that lived, he had in reality only 22 per cent. Kuhn followed the fate of the children in 46 cases of placenta prævia, and found that two months

after birth only two of them were alive. And Müller states a placenta prævia child has only three chances out of ten of being born alive; and as Virchow shows that nearly one out of every three children born under all circumstances in Berlin die within the first year, its remaining chances would be almost gone before even its time came for measles, whooping-cough, scarlet fever, and the various other diseases that we may almost regard as its necessary trials, before it reaches a time when the value of its life may be in any way compared to that of its mother; so that as far as we can at present manage the treatment of placenta prævia the chances of saving the child need not prevent us from inducing premature labour. *Therefore, I would strongly urge that premature labour be brought on as soon as we know that we are dealing with a case in which the placenta presents after the seventh month of pregnancy, and even before then should the bleedings be serious, frequent, or continuous.*

Before discussing the best means of inducing labour in these cases, let us consider some of the principal methods of treatment recommended for placenta prævia, the point being to effect delivery with as small a loss of blood as possible, and with less risk to mother and child.

The older writers, even as far back as Giffard and Portal, knew that the placenta might be implanted over the os, or (as they thought) attached to the cervix; and some of their instructions for treatment are both quaint and curious, though scarcely instructive. We find Guillemeau and Mauriceau having very clear ideas of its existence, and recommending the rapid and forcible emptying of the uterus at all hazards—the *accouchement forcé*. Rigby has written a very clear description of it in his work on "Hæmorrhage," and appears to have been the first to have made a distinction between "unavoidable" and "accidental" hæmorrhage, and wrote that "manual extraction of fœtus by the feet is absolutely necessary to save the life of the mother in unavoidable hæmorrhage, but in accidental hæmorrhage is not required."

The first change from this method of treatment, viz., *puncture of the membranes*, is generally attributed to Puzos, but was described by Mauriceau fifty years before him, as he distinctly says: "The vessels of the uterus, which were open, become shut by the contraction of its proper substance as soon as the waters of the infant which held it extended are evacuated from it." This practice was largely followed by Ramsbotham, and in the present day is strongly recommended by such eminent authorities as Barnes and Playfair. I have found it of service in lateral presentation, but its use in the other forms is not to be relied on. In complete presentation it is difficult of accomplishment; and besides, an objection I have to it is this, if it fails, as it often does, it renders version, which may have to be fallen back upon, more difficult and dangerous; therefore I reserve it for cases of lateral presentation of the placenta where the head presents, for when the waters escape, the head presses against the placenta, and the forceps can be applied, provided the head presents, which, be it said, it frequently fails to do in cases of placenta prævia.

The next mode of treatment which we need consider is the *separation of the placenta from the uterus*, which was so ably brought before the profession in a communication laid before the Medico-Chirurgical Society of Edinburgh in 1844 by the late Sir James Simpson. He was led to adopt this practice from a consideration of eight cases in which he found that the hæmorrhage ceased on the complete expulsion by natural means of the whole placenta before the birth of the child, and finally put on record from various sources 141 cases of this occurrence, and it may interest the Society to learn that some of these cases were contributed by the late Doctors Tulloch, Greenhow, and Harcastle of this city, and he arrived at the following conclusions:—

1. The complete separation and expulsion of the placenta before the child in cases of unavoidable hæmor-

rhage is not so rare an occurrence as accoucheurs appear generally to believe.

2. It is not by any means so serious and dangerous a complication as might *a priori* be supposed.

3. In nineteen out of twenty cases in which it has happened the attendant hæmorrhage has either been at once altogether arrested or it has become so much diminished as not to be afterwards alarming.

4. The presence or absence of flooding after the complete separation of the placenta does not seem in any degree to be regulated by the duration of time intervening between the detachment of the placenta and the birth of the child.

5. In 10 out of 141 cases, or in 1 out of 14, the mother died after the complete expulsion or extraction of the placenta before the child.

6. In seven or eight out of these ten casualties the death of the mother seemed to have had no connection with the complete detachment of the placenta, or with results arising directly from it; and if we do admit the three remaining cases, which are doubtful, as leading by their occurrence to a fatal termination, they would still only constitute a mortality from the complication of 3 in 141, or of 1 in 47 cases.

7. On the other hand, under the present (1844) established rules of practice, 180 mothers died in 654 cases of placental presentations, or nearly 1 in 3.

He first deliberately put the method in practice on the 1st of October, 1844, but the placenta had been artificially removed by others previous to Simpson, and cases are recorded as instances of malpractice by Collins, Ramsbotham, Cripps (of Liverpool), Lowenhardt, Baudelocque, &c. Ramsbotham describes a case so graphically that it is worth recording in his own words. He was summoned by a doctor to come and help him in a case he was attending, but before Ramsbotham left his house he received a second message from the doctor saying that he need not come, "as the woman was better and doing well." When on next meeting the doctor he asked what was the nature of the case, the following conversation ensued:—"It was the strangest case I ever saw; it was a placental presentation with the most violent flooding, but I got it away." "Got what away?" says Ramsbotham. "Why, the placenta," says the doctor. "What, before the child?" asked Ramsbotham, in astonishment and horror. "Yes, before the child," said the doctor, "and the flooding ceased and the woman did well, and the child soon followed the after-birth." Simpson thought the placenta was the source of the bleeding; this, however, has now been established not to be the case, as the hæmorrhage comes from the open mouths of the uterine vessels, and Barnes has drawn attention to the fact that in the majority of cases it is not necessary to separate the whole placenta, for there is a natural spontaneous arrest of hæmorrhage attained when that part of the placenta which has grown within the lower zone has been detached, provided uterine contractions concur, for it is on these we must depend to stop the hæmorrhage, and the reason of the cessation of hæmorrhage, though not explained by Barnes, is, I believe, this—when the placenta is completely expelled, the uterus is able to contract and close the open mouths of its vessels, as it does in twins, where the first placenta is expelled before the birth of the second fœtus; but when the placenta is only slightly detached, the connecting vessels being only partially torn are kept on the stretch, and so the chief source of the hæmorrhage is from the line of juncture of the uterus and partially-detached placenta; but when the placenta is sufficiently detached to become flaccid it does not drag on the vessels, and so permits them to contract, which they readily do provided the uterus is contracting; hence it is desirable to pass in a finger and separate the placenta well round the os to permit this flaccidity to occur. The extent to which this should be done will vary in different cases, depending on various circumstances, such as position of the fœtus, amount of liquor amnii, strength of pains, &c., but it generally cor-

responds to the extent which the placenta would be spontaneously detached to admit the passage of the foetal head, the largest circumference of which is about equal to a circle with a diameter of  $4\frac{1}{2}$  inches; or, according to Matthews Duncan, the plane at which spontaneous detachment ceases is reached at a distance of  $2\frac{1}{2}$  inches by following the curve of the lower segment, and of  $1\frac{1}{2}$  inches if measured in the plane of the uterine axis.

(To be concluded in our next.)

## ON SOME OF THE DETAILS AND RECENT MODIFICATIONS IN THE ANTISEPTIC TREATMENT OF WOUNDS.

An Address delivered before the Biological Association of the University of Dublin.

By KENDAL FRANKS, M.D., F.R.C.S.I.,  
Surgeon to the Adelaide Hospital, &c.

MR. PRESIDENT AND GENTLEMEN,—I have felt for some time that it was incumbent upon me to make a communication to the University Biological Association, as a small acknowledgment of the honour you conferred upon me in electing me one of your honorary members. I think I cannot fulfil that obligation better than by bringing before you a subject which is invested at the present time with great interest, namely, the antiseptic treatment of wounds. My chief object in doing so is, that certain modifications have been introduced into the method, more especially in Germany, where the principle of antiseptic surgery is, I may say, universally recognised, modifications which I believe tend to render antiseptic surgery more simple, more efficient, and more readily adapted whether to public or private practice, whether in town or country. I do not intend this evening to discuss the question of the *value* of aseptic surgery. I will take for granted that you are all quite satisfied on that point. This question has been fully debated, and has become threadbare, and no useful end is now to be gained by going over the arguments in favour of a method of practice which the experience of the last ten years has fully established. If your experience of the method has been one of failure, if you have seen wounds inflame and suppurate or run an unhealthy course, do not blame the principle upon which your practice is based, blame rather the manner in which the principle is applied. And here let me ask you to discriminate clearly in your minds between the antiseptic principle and the various methods employed to put that principle in practice. The principle is now recognised to be unassailable. It simply tells us that we must keep all forms of organisms out of our wounds from beginning to end, if we wish to obtain the best results. This is the foundation on which we must build, and here we find unanimity among antiseptic surgeons. When, however, we come to the question as to what is the best method to adopt in order to carry out this principle most thoroughly, we find a wide divergence of opinion. All aim for the same goal, but they travel along different roads; what we must seek for is the road which is the shortest and easiest, and yet never fails to reach the desired end.

Now, gentlemen, before we can fully appreciate the efforts which are being made to secure asepticism in wounds in the simplest and surest way, I must ask you for a few moments to consider in detail the *matériel* of Lister's method. This method you have doubtless seen frequently employed, and when all proper precautions are taken, you have seen that it is effectual in keeping operation wounds aseptic. But even those who have had the largest and most successful experience of this method, are not satisfied that with it we have reached perfection, or that it leaves nothing more to be desired. For convenience sake we may consider that Lister's method, in common with all methods,

may be divided into three stages, namely, the securing of asepsis before, during, and after, the completion of an operation. It is in this third stage, which we may take to begin at the time when the wound has been finally closed, and before the dressings have been applied, that the greatest amount of changes have been introduced or suggested, and therefore, to this stage I will, in the first instance, direct your attention. In a typical Lister's dressing, when the drainage tubes have been inserted and the wound stitched, a piece of so-called protective is in the first instance applied. This is carefully prepared oil-silk, and is impervious to carbolic acid. It is itself rendered aseptic by being dipped in a solution of carbolic acid immediately before being applied to the wound. Its object is, as its name implies, to protect the sensitive wound beneath from the irritating effects of the carbolic acid. I allude to this now because the use of the protective is often misapprehended. Many think that its object is to prevent the dressings sticking to the wound, and some seem to think that it is an advantage in keeping the wound moist. Now, as I hope presently to show you this latter is a serious drawback to it. Its real use is easily understood, when you remember that the carbolic gauze which invests the wound in a typical Lister's dressing, contains nearly 5 per cent. of carbolic acid—the warmth of the skin over which it is applied helps to volatilise the acid, and thus we would have the wound constantly exposed to the irritation of an atmosphere of carbolic acid, were it not protected from it by a material which was impervious to it. This seems so evident that it is hardly worth while to call your attention to it, and yet it is necessary to bear it in mind, for I have seen the protective applied over the deep dressing, and, again, some manufacturers in recommending the protective they make, assure you that it is prepared with carbolic acid, thus bringing about the very thing we try to avoid by its use. Over the protective then, we apply what is called the deep dressing. This is composed of several pieces of loose gauze, dipped in carbolic lotion immediately before being applied, and then squeezed nearly dry. Using the gauze this way, in loose pieces, enables us to accommodate it to the various inequalities of the surface. It is very important to remember that those loose pieces, which lie next to the wound, must be dipped in the lotion immediately before applying them. The object of doing so is this: It is almost impossible to insure that some particles of dust should not fall on the gauze during some period of its transit from the manufacturer's to the wound. Should this dust happen to lie *between* the different layers of the gauze dressing, the carbolised atmosphere generated by the heat of the body soon renders such particles inert. It is as if it were attacked on both sides by the antiseptic. But it is different with the gauze which lies immediately in contact with the wound. Here the dust may penetrate into the wound before it has had time to be rendered inert. It finds a suitable soil in the discharges which come from the wound, or lie in it, and these discharges though previously aseptic are not antiseptic, and have no power to prevent the development of any germs which may have gained an entrance. Hence it is most important to insure that no organisms capable of doing mischief shall remain in the deep layers. The amount of the deep dressing depends of course on the quantity of discharge which may be anticipated. Over this deep dressing again we apply the outer dressing, which consists as you know of nine layers of gauze. There is no special charm in the proverbial nine layers, eight or twelve layers would do as well, but nine are generally used on account of the greater facility of folding. Between the eighth and ninth layers there is inserted a piece of mackintosh. The object of this you know is to prevent the discharge soaking rapidly through the dressings at a point opposite to the wound, and so necessitating their being changed. The mackintosh compels the discharge to travel under the dressings until it reaches the edges, and thus the whole of the gauze is utilised.

Finally, the dressings must be secured in their place with gauze bandages, and special care must be taken to see that the edges of the dressings are kept in close contact with the skin. This is generally accomplished by means of an elastic web bandage.

Now a very important question arises in connection with these dressings, and that is, when should the dressings be changed? If there is much discharge from a wound during the first few days the dressings must be changed frequently. They will often require to be changed within twelve hours, and nearly always within twenty-four hours. Sir Joseph Lister is in the habit of changing the dressings in nearly all cases the day after operation, and afterwards only as occasion may require. As a general rule the dressings must be changed as soon as the discharge makes its appearance at the edges of the dressing. This may compel us to change the dressings every second or third day, but in no case should a carbolic gauze dressing remain unchanged for longer than a week; for the carbolic acid being volatile, every day the strength of the dressing diminishes, and soon it reaches a point when the amount of the antiseptic present is no longer able to prevent the development of organisms. But even before this point is reached the appearance of discharge at the edges of the dressings compels us to change them. For under these circumstances we have a pathway leading from the outer air to the wound, which is filled with a fluid most favourable to the development of organisms, and it is impossible that this fluid should abstract sufficient carbolic acid from the dressings to render it antiseptic itself, for we know with what tenacity the resin holds the acid. If under such circumstances we neglect to change the dressings, it is remarkable with what rapidity organisms develop in the discharges, and make their way to the wound.

Such, then, are, shortly, the materials employed in, and the method of, applying a Lister's dressing. Whilst fully recognising the value of such a dressing, antiseptic surgeons everywhere have been attempting to modify and to improve it. I say modify and improve, for many modifications which have from time to time been suggested are not improvements, for they fail often to ensure asepticity. The objections which have been raised by earnest workers in this field, and all other objections we may at present neglect, may be summed up under the following heads:—

*First, the dressings are expensive.*—The gauze alone, to buy, costs about 3d. a yard, although if we make it ourselves it would cost a little over 2d. Now, suppose our outer dressing of wire layers is eighteen inches square, we should require 2½ yards of gauze one yard wide. That alone would cost 6½d. When we add to this the price of the gauze used for the deep dressing and the bandages, the price of the mackintosh and the protective, I think you will agree with me that to put down the price of such a dressing at one shilling is not an exorbitant estimate. Could we leave these dressings on permanently—that is, till the wound was healed, we should not regard this as an expensive dressing; but when we are obliged to renew them frequently, the price becomes a serious item, especially in a hospital where large quantities are daily employed. I do not mean that the price should debar us from using them could we obtain nothing cheaper, which would at the same time be equally efficacious, but it should certainly stimulate us to seek for such a cheaper dressing.

*Secondly—The antiseptic employed is volatile.*—This obliges us, as I have already shown, to change our dressings frequently. The gauze when properly prepared contains about 1 in 20 of carbolic acid, but if it is exposed to the air it loses the acid rapidly, so that in half-an-hour it will probably not contain more than 1 in 30 or 1 in 40, according to the temperature of the air, and thus, when applied to the wound, it may not have a sufficient quantity of antiseptic present in it to render it safe.

*Thirdly—Its power of absorption is very small.*—When you buy ordinary gauze in a shop—manufactured book-

muslin, as it is called—you will find that it invariably contains a certain amount of fatty substances, which interfere with its power of absorption. If you wash such gauze and boil it with carbonate of soda, its absorbing powers are greatly increased, for the fat is thereby removed. I tested it in the following way:—I weighed an ounce of this dry gauze; I then allowed it to soak in water till it was saturated. It was then suspended, so as to allow the excess of water to drain from it, and was then weighed again. Its weight was now a shade over 6 ozs.; in other words, it was capable of holding five times its own weight of fluid. It might be objected that this was not an accurate way of testing it, as the fluid was not the discharge from a wound, nor did soaking the gauze in fluid correspond to the manner in which gauze absorbs when applied as a dressing. But these objections do not really hold good, for we are not concerned at present to inquire the exact amount that a particular dressing will absorb from a wound, but the relative powers of absorption that different materials possess, and we need then only care that the same method of testing is applied to all. Now, if we apply this method to Lister's carbolic gauze, we find, as we should have suspected, that its absorbing power is very small. I tested not only the gauze which we manufactured ourselves at the Adelaide Hospital, but also the best gauze I could buy in Dublin, and which had been imported from England. The results with both were identical. After twenty-four hours' immersion in water, they had absorbed or taken up only 1½ times their own weight, and after three days only 2½ times. Hence we see that carbolic gauze, on account of the paraffin and resin used in its manufacture, absorbs very slowly, and absorbs comparatively very little.

*Fourthly—It keeps the wound moist.*—It is well known that the more concentrated a fluid is, the more it becomes an unfavourable soil for the development of the lower organisms, and that the complete drying of the secretions from a wound forms an almost certain obstacle to putrefaction. This is the principle of scab-healing, and ever since the days of Hunter, surgeons have attempted to procure rapid healing of a wound, by trying to form an artificial seal over it; but all these attempts were unsuccessful, because they failed to remove the chief danger, namely, the retention of the secretions beneath the scab. If then we wish to obtain the advantages of rapid healing under a scab, formed by the drying of the secretion on its surface, we must provide means for carrying off the secretions rapidly from the wound, and this is effected by free drainage, and by the use of some highly absorbent dressing. The great advantage, from an antiseptic point of view, of keeping the wound dry by carrying off its discharges rapidly was well illustrated by the experiment related by Mr. Sampson Gamgee at the meeting of the International Medical Congress in London in 1881, (a) "Take two pieces of fresh meat of equal thickness and weight. Place one between two pads of absorbent gauze and cotton, and wrap the other in lint soaked in water, with a covering of oiled silk or gutta percha. The first piece, as I have often proved by experiment, will continue dry and sweet, long after the meat in water dressing has become a rotten and stinking mass." In the carbolic gauze dressing, it is impossible for the wound to be kept dry, for next the wound we have the protective, and outside all the dressing we have the mackintosh which renders drying of the secretions impossible.

*Fifthly—The great difficulty in obtaining and in keeping the carbolic gauze in a reliable condition.*—I have already alluded to the rapidity with which the carbolic acid may evaporate from our dressings, it is therefore of the greatest moment that every precaution should be taken to insure the carbolic gauze being efficient; and I am convinced that it is to this unreliableness of the gauze that more failures in antiseptic treatment are due than to any other cause. Look for one moment at the vicissitudes through which the gauze has to pass before it reaches

(a) "Transactions," Vol. II, p. 349.

your hand. All that which you buy in the shops is for the most part manufactured in or near London. It is brought over to Dublin, and has to pass through the hands of many who are either ignorant of the care which the gauze requires, or who are antiseptic sceptics, before it comes in to your possession. I will give you an instance. Not long ago I went into a shop in Dublin and saw on the counter a heap of nicely folded gauze which had been taken out of the case in which it had come over, and was awaiting the "convenient season" to be stowed away. It lay there uncovered, exposed to the air and the dust of the shop. How long it had lain there I cannot say, but of one thing I am sure, that such gauze could only bring discredit on antiseptic surgery. Stimulated by failures for which we could not account unless they were attributable to the bad quality of the gauze, about two years ago we determined to manufacture what we required in the Adelaide Hospital. I need not weary you with the details of the process of making carbolic gauze, suffice it to say that we soon discovered that what we made was far better than any we could buy and gave far better results. From a comparison of it with that which we bought, by weighing equal quantities before and after it was charged, I could not but come to the conclusion that the gauze prepared elsewhere and imported into Dublin, was not made according to Lister's directions, and that it did not contain the proper quantities of either resin, paraffin, or carbolic acid. But even after we have made the gauze, great care must be taken with it to prevent its deterioration. The precautions which we adopted in the Adelaide Hospital were these. As soon as the gauze was charged, it was loosely shaken out and at once put into a large chest lined with tin and air-tight. It was kept in this until required for use. When a ward required to be supplied one of the nurses of the ward took down an air-tight tin box, large enough to hold a supply of gauze which would last from a week to a fortnight. This was filled with the prepared gauze, closed and locked, and in this way taken back to the ward. Here it was folded into convenient sizes, some torn up for bandages and rolled, some cut into small pieces for deep dressings and then carefully replaced in the box, and the box locked. The folding of the gauze was done on a waterproof sheet previously sponged over with carbolic lotion. Of course we must depend, to a large extent, on the nurse to see that all these precautions are taken, and that the box is used for no other purpose than to hold carbolic dressings. But these details will show you what care must be used in preserving the gauze in a proper state for use.

(To be concluded in our next.)

## DEAHNA ON DRESSINGS.

Translated from *Schmidt's Jahrbucher*.

(By T. ESMONDE CAHILL.)

(Continued from page 439, last vol.)

[We now come to the new surgery. It is called by various names:—The Bismuth dressing, the plan of secondary suture, the *Dauerverband*, and the peat mould application. But all these names can be sunk in one—the great dry treatment.—TRANSLATOR.]

**Bismuth.**—Kocher grounds his recommendation of subnitrate of bismuth on the possibility therewith of dispensing with drainage, and thereby bringing about immediate union of the greater part of the wound. Secondary suture is an aid. At the start the powdered bismuth was strewn on the wound. Later a ten per cent. solution, until finally it was found that a one per cent. mixture fulfilled all the demands of antiseptia. An emulsive mixture may be rubbed in or syringed in after the operation, and at the changes of dressing. When the wound had been sutured, then a thicker mush (*Brei*) of bismuth is applied which dries to a crust. The first dressing is made with shreds of hydrophilous material.

A series of experiments has determined the fact that bacteria are not capable of developing in preparations of bismuth. Poisoning phenomena, however, are very common. Acute stomatitis with swelling of the gums, the tongue, and the throat, loosening of the teeth, and blackening of the edges of the gums, intestinal catarrh, and desquamative nephritis are all observed. After the operation the sutures (silk) are inserted in all cases in which the rapid termination of the case is looked for, though not tied, but a bismuth dressing applied. If bleeding is not completely stopped, bismuth tow is applied. After from 12 to 48 hours (depending on the amount of oozing (*nachblutung*)), the wound is hermetically closed. *Because secondary suture allows itself to be applied to all wounds which are capable of union at all, Kocher contends that the evolution of wound secretion after from half to one day is not a necessary consequence of traumatism.* Part of the favourable result is to be attributed to the drying of the wound surface by the astringent action of the bismuth. Thirty-six cases showed very favourable results. Kocher finds that the bismuth fails to work upon the cocci, and only renders the soil (*narkboden*) incapable of developing micro-organisms. Riedel finds that bismuth works well in flesh-wounds, but brings on pleuritis in the pleura, and extensive adhesions in the peritoneum. It is no good in abscess or erysipelas. V. Langenbeck praises bismuth, but for scab-healing he prefers iodoform. Petersen finds great disadvantages in bismuth, and substitutes oxide of zinc. It is cheap and does not produce poisoning symptoms.

**Acetate of Alumina.**—Burow, Bruns, and Billroth have all designated this as an extremely useful disinfectant. Pinner found that a 0.5 per cent. solution was sufficient to protect substances on the point of decomposition; that solutions of 1.5 to 2 per cent. would kill germinating bacteria. A solution of 2.4 per cent. was always sufficient to keep down the proliferation of bacteria.

**Technique.**—Essentially Listerian. Purify the field of operation and the instruments with a 5 per cent. carbolic solution, since the acet. al. does not saponify and does corrode. For other uses, and for a spray, apply a 2½ per cent. solution. Anæsthesia in the hands seldom observed, but they become raw. Suturing with catgut or more rarely Czerny's silk. Bandages, gauze preserved in a 5 per cent. solution of alum. From within, outward—protective silk gauze, salicylic wadding (10 per cent.) calico bandages. Bandage dispensed with after eight days. For permanent irrigation a 0.5 per cent. solution suffices. The acet. al. spray actively astringes and dries the wound, so that capillary bleeding is controlled. A permanent solution is not attainable, evaporation evolves hydrate of alumina.

**Preparation.**—400 grm. acid. acet. dil. offic. (P. Germanica) is applied for dissolving 500 grm. patent alumina; decant and filter. The resulting fluid gives in 100 parts about 4.5 parts anhydrous alumina, or about 15 per cent. of the bi-acetate (*Zweifach essig-saure*). It was found that a 700 to 400 solution produced eczema.

**Statistics.**—In Pinner's hands, from the 20th of June, 1871, to the 1st of August, 1881, the results were very favourable—more favourable than those with the previously used Listerism. Of course you cannot make a permanent dressing of any moist application. The spray was withheld on account of the conductivity of infection possessed by the air. In the ward in question in Freiburg Academ. Hospital there were:—Patients, 2,183; operations, 708; tracheotomies, 119; erysipelas (mild), 5; erysipelas (fatal), 1; pyæmia, 0; septicæmia, 1—doubtful. Poisonous effects not observed. Wound cavities after necrotomies, and so forth, can be filled up with aluminated charcoal. This method has also been found very useful on the living subject in extirpation of the rectum.

On the principle of keeping away all irritation, mechanical or chemical from the wound, Esmarch has inaugurated, and Neuber has continued, to improve, the antiseptic *danerverband*. Neuber was brought to in-

investigate this subject by the odium attached to artificial blood drains on account of parenchymatous coozing. Neuber acknowledges the presence of parenchymatous coozing, but thinks it is over-estimated. Careful application of ligatures previous to the loosening of Esmarch's tourniquet, elevation of the limb, compression of the flaps, irrigation with ice-water, sufficed to prevent abundant coozing (*nachsickern*) of secretion, so that the first dressing remained on four days on an average. Particular care afterwards enabled him to leave it on until the wound was healed all to the drainage canal and suture holes. There was still wanting only an absorbable suture and drainage material to produce complete healing under *one dressing*. He took catgut and decalcified bone. From within outward—*knüllgaze* fixed by means of carbolic gauze bandages. The same must more than amply cover the wound in a layer of one to two fingers thick. The result is a spindle-shaped limb. Further inequalities, if any, are filled with salicylic wadding. On the most dependant part of the wound an inch thick of wadding is superimposed. Now follows the 9-folded Lister gauze. This projects beyond the wound on all sides at least 3 to 5 hands breadths, and must at both borders be lined with a hand's breadth of inch thick salicylic wadding. The gauze will be strongly compressed, and enveloped by prepared gauze bandages. An elastic compressive bandage outside completes the dressing. In the thirty-six cases communicated, this dressing remained on up to the twentieth day. In eight cases there was absolute healing after the first change of dressing. In four the wound gaped a little, in nineteen *prima-intensio* had come on in the whole extent of the wound line, all to quite small spots which mostly corresponded with the drainage. Of three cases of ovariectomy there were two deaths from peritonitis. The same in a case of resectio ilei. In an ablatio mammæ there came on fatal septicæmia in sequence of retention of secretion. In four cases there was moderate suppuration-odour in as many.

*Hautdurchlochung*.—Drainage is facilitated by hoieing the skin with a skin punch.

*Peat-Mould*.—Finally, there was found in peat-mould a dressing material which by its strong absorptive and drying powers greatly increased the usefulness of the *daner-verbana* compound. It was first used by a turf cutter, who cured a complicated fracture of the forearm in ten days without a drop of pus. Neuber used the sawdust of white peat-mould. This material possesses in the dry state an extraordinarily great absorptive power for fluids, especially water and blood, for pus less: it takes up nine times its own weight in water or blood. It further exhibits considerable power of absorption for bad smelling stuffs, and finally, it was found that portions of meat and blood enclosed in the centre of a peat ball resisted decomposition, at least as long, perhaps longer than in a ball of 5 per cent. carbolic wadding.

*Technique*.—Purify the wound with a two and-a-half per cent. carbolic solution, furnish it with absorbable drainage tubes or punch holes and suture. Then place a small 2½ per cent. iodiform-peat cushion, over that a large carbolic (5 per cent.) peat cushion, make fast the whole with a gauze or water-glass bandage. Loosen the Esmarch's tourniquet when the dressing is applied; in this way the operation is completely bloodless. There never was secondary hæmorrhage.

*Statistics*.—Cases 212; deaths 3; dressing ran full course in 198; dressing prematurely removed in 11; complete healing in about 167.

Gaffky has experimented on peat and offers the following axioms:—(1) Peat is not free from fertile germs of lower organisms; (2) peat possesses no lethal power over bacteria, it is not a disinfecting substance; (3) antiseptic power in the sense that saturated with proper nutritious fluids, it *completely* prevents the multiplication of lower organisms in the same, peat possesses none (4), on the other hand, peat can under such circumstances delay up to a certain point the multiplication of the lower organisms.

In spite of these results of his experiments Gaffky believes that on account of its considerable power of absorption and its elasticity peat may be safely recommended.

*Moor-moss*.—Hielk finds the absorption power of peat enhanced in the *sphagnum* which is developed after the withering of moor-moss. He recommends it as a dressing.

## HISTORY OF THE PROGRESS OF LARYNGOLOGY FROM THE EARLIEST TIMES TO THE PRESENT.

By GORDON HOLMES, M.D.,

Physician to the Municipal Throat and Ear Infirmary, London; Consulting Physician to the Sheffield Ear and Throat Hospital.

Il importe beaucoup de connaître l'histoire de la science à laquelle on s'attache.—*Boerhaave*.

### EPOCH I.—THE PRE-LARYNGOSCOPIC AGE.

(Continued from page 165.)

In 1829 the growing importance of laryngeal pathology was first signalled by the production of a separate treatise devoted to diseases of the larynx in general. The author of this work was J. F. H. Albers, (1) Professor of Anatomy at Bonn. And in this country the necessity of studying laryngology was emphasised by the London College of Surgeons proposing in 1836 diseases of the larynx as the subject of their annual Jacksonian prize. The successful essay was written by Frederick Ryland, (2) of Birmingham. This author deserves the great credit of being an original collector of the scattered information existing on his theme, of illustrating it with fresh examples drawn from his own experience, and for the reduction of it independently to a system. We cannot, however, attribute to him any special step in advance; he is, in fact, considerably behind his predecessor, Albers, as well as Trousseau and Belloc, whose work, published about the same time as his own, also claims to be classed as one of the primitive treatises on diseases of the larynx.

But in Albers (3) we are compelled to recognise a laryngologist of far greater calibre than the state of the science at the time could give us any grounds to expect. He was indisputably the first observer who contemplated a system of laryngeal pathology complete in almost all its divisions, although the resources of his art did not at the time permit the full clinical exemplification of his conceptions. Thus, he is the first writer who treats in definite terms and separate sections of simple catarrh and chronic hypertrophic catarrh of the mucous membrane, of syphilitic and tubercular ulcerations (to a great extent anticipating Trousseau and Belloc), of disease of the cartilages, growths, &c., and especially paralysis of the larynx. In dealing with the latter department he relies on the experiments of Le Gallois for the construction of a framework which he tries to fill in with clinical instances, but he is also misled by Magendie's erroneous theory of innervation. He is, however enabled to distinguish two classes of laryngeal paralysis, namely, *aphonia paralytica*, in which the voice only is affected, and *laryngo-plegia*, when breathing is also interfered with, "Occurring probably," as he remarks, "when isolated muscles, especially *musculi dilatores glottidis*, are paralysed." He considers that this paralysis is likely to be present in œdema of the glottis, and croup, being then the chief cause of dyspœna, and also that it may be brought about by tumours, such as aneurism of the arch of the aorta, enlarged glands, &c., disposed so as to press on the recurrent nerve, or if by ulceration or caries the cartilages and muscles should become separated.

In 1846 our history first leads to the other hemisphere, in which year Horace Green, (4) Professor of Medicine at New York, demonstrated in practice the conception of Van Swieten as to the pathological interest of the mucous glands, of the pharyngo-laryngeal tract of mucous membrane. Under the name of "follicular diseases of the air passages," Green well described and illustrated by chromo-lithographs the granular state of the pharynx, the counterpart on a

larger scale of the often concomitant affection of the larynx, thus revealing the pathology of the disease often spoken of vaguely as "clergyman's sore throat." He considers fully the etiology of the malady, which he determines to be fundamentally allied to struma and debility, but he does not distinguish between the comparatively mild lesion ordinarily met, and the severe morbid process leading to ulceration, to which we shall have to allude further on as probably peculiar to phthisis.

The existence of laryngeal neoplasms and tumours was clearly recognised from the beginning of this period, and numerous such cases of peculiar and ordinary type were, from time to time, reported. Thus Pravaz (5) in 1824 gives the instance of a girl, *æt.* 26, who for six years suffered with a tumour of the larynx which could be felt on passing the fingers through the mouth to the upper part of the organ. On a certain day two hard stones, of the size of a small pea, were expectorated, and recovery ensued. The same author cites the case of an officer who died somewhat suddenly from suffocation, and on post-mortem examination two hydatids, transparent and ovular, as large as a nut, were found under the epiglottis, occupying in part the ventricles. The first writer who devoted a special treatise to laryngeal growths was H. G. Urner, (7) of Elberfeld, in 1833, on the text of a case observed by Albers. This was a fatal case in a man, *æt.* 54, where a round and fleshy tumour, the size of a nut, was discovered fixed by prolongations to both vocal bands. In 1850 almost all the scattered cases were collected in a treatise, exhaustive up to date, by C. H. Ehrmann, (8) Professor of Medicine, and Director of the Museum of Anatomy at Strasbourg. This work includes thirty-six instances, of which two are from the author's own experience, and five from animals. Nineteen of them are reproduced, in natural size, in skilfully executed lithographs. Ehrmann endeavours to explain the histology of laryngeal polyps, but owing to his limited personal observations and the vagueness pervading the descriptions of others, he can only conclude that some are of a fibro-cellular or fibroid structure, whilst others result from a hypertrophy of the tissues of the mucous membranes, chiefly the epithelial elements. In 1852 a treatise on polypi of the larynx was published by Horace Green, (6) who added eight cases met with in America (four of his own) to those already enumerated by Ehrmann, and discoursed intelligently concerning the symptoms of such tumours. To two of his own instances he applied the term "cauliflower excrescence," and "encephaloid."

The subject of croup attracted much attention during this period, so that the literature of this disease became very extensive, a circumstance which, though it did not bring forth much scientific advance, rendered the objective recognition of the malady very facile and widespread. As early as 1778 C. F. Michaelis, (9) of Göttingen, wrote an exhaustive essay on croup, a work of almost scholastic ingenuity in the detection of points for reflection and discussion. We need, however, to notice only the views current as to the nature of the false membrane. Michaelis refers to the observations of Böck and Salomon (10) that it contains longitudinal fibres and may often be seen to be streaked like the manual epidermis. His own conclusion (a development of that of Ghisi) (11) is, that this production is "a true polypus of the trachea," of lymphatic origin, and inorganic nature, thus differing entirely from the organic polyps of the uterus, nose, &c. Hence he proposes and adopts the name of *angina polyposa* instead of croup. In 1808 Antoine Portal, (12) Professor of Medicine at the College of France, wrote on croup at considerable length in a literary and observant manner. He was followed by numerous authors up to this period, any record of which, except a mere bibliographical one, would only offer to the reader a web of prolix speculation tending to obscure, rather than to elucidate the phenomena of the disease. Thus it will be perceived that, on the whole, the pathology of croup remained *in statu quo*.

*Mutatis mutandis*, many of the remarks in the last paragraph can be applied to spasm of the glottis. Numerous monographs caused practitioners to be alert in recognising cases, but the pathology was not elucidated. The first rational explanation was given in 1841, by Marshall Hall, (13) who ascribed the malady uniformly to reflex action, an etiological conception which, considering the wide distribution and varied connections of the pneumogastric nerves, must in most, if not in all cases, be received as satisfactory. Hall considered that the peripheral source of the spasm might

exist in one or more of three regions, viz., the dental, gastric, and intestinal. Thus the external irritant would generally be teething, stomach derangement, or worms. To reflex spasm of the glottis Hall also relegated instances of choking, or a foreign body lodging at the top of the œsophagus.

In 1808 an important advance was gained in the pronunciation by G. S. Bayle, Professor of Medicine at Paris, of the first discriminative description of œdema of the larynx. (14) His memoir was based on seventeen cases seen by himself, in which there was only one recovery. The various symptoms of the disease were fully described, as well as the chief post-mortem feature of serous infiltration of the glottis which produces the fatal swelling. (15) After the time of Bayle the subject was kept well in view and many papers relating to it were issued. In 1852 the observation and discussion of the disease culminated in the production of a very elaborate work by F. Sestier, also Professor of Medicine at Paris. In a volume of nearly 500 pages this author amassed all the information, literary, etiological, therapeutic, &c., that could illustrate or be drawn from the numerous cases previously published, amounting to about 215. The fact that Sestier makes eleven varieties of the malady, the division resting principally on etiological distinctions, is sufficient to indicate the minuteness of his analytical operations.

*Treatment.*—This department underwent great development, especially as to the local medication of the larynx, but much also was done towards the perfecting and extension of operative measures.

In general therapeutics we may chronicle the discovery of iodine in 1812 by Courtois, of Paris, and its first use in syphilis in the form of iodide of potassium, claimed by James Copland, (16) of London, as having been made by himself in 1825.

We have seen that the ancients prescribed inhalations, insufflation of powders, revulsives to be applied to the neck and remedies (hypoglottides) to act on the windpipe by being swallowed during slow dissolution in the mouth. Such methods, however, though occasionally employed, were never popular or extensively resorted to until Trousseau and Belloc re-enumerated, discussed, and gave them a new prominence in their essay of 1837. But the devices of these observers as to treatment were not limited to the refurbishing of old measures, for they also invented some new ones of great value. Thus they were the originators of the direct application of solutions to the larynx, a proceeding which they effected in three ways:—(A), a spill or twist of suitable paper was bent into a curve at one end, which was dipped in the fluid (they preferred a weak solution of silver nitrate) and then passed down to the larynx by the mouth; (B), a stick of whalebone similarly curved with a fragment of sponge attached was used in the same manner; (C), a small syringe with a curved pipe terminating in a rose was employed to inject the liquid in a fine shower.

Independently of Trousseau and his colleague, Horace Green, a year or two later (17) devised and carried out with no less ingenuity the application of solutions to the larynx. Like those practitioners, he preferred nitrate of silver, and used a curved whalebone with sponge attached. Tracheotomy was extensively practised. Trousseau and Belloc refer to seventy-eight operations in their own practice, of which five were undertaken for the relief of dyspnoea in laryngeal phthisis (so-called) and seventy-three in croup. In the latter disease, however, some surgeons disapproved of it, Porter, (18) of Dublin, for example, conceiving the severity of the constitutional disturbance as the real cause of death. The improvements in the operation relate solely to the construction of the canula. Trousseau and Belloc allude only to the single straight tube, but in this country a single curved tube, answering to a quadrant, and tapering considerably towards the inner end, was in general use many years previously. Such a tube is recommended by Robert Liston, (19) of London, in 1831, the object of the diminishing calibre being the compression of the sides of the wound to prevent hæmorrhage by the thick external portion. The history of the tracheotomy canula is, however, full of vicissitudes. The first suggestion of the modern tube, which in no way resembles, and perhaps is not even related to that of Casserius, seems to emanate from A. G. Richter, (20) Professor of Medicine at Göttingen in 1776. In 1784 Antoine Louis, (21) the greatest civil and military surgeon in France at that date, whilst reproducing the figures of Casserius, yet showed a quadrant conical tube of the form usually employed in his time

Nevertheless in the same year Benjamin Bell, (22) of Edinburgh, after considering the propriety of using Richter's curved tube, decides in favour of a straight one, his reason being that an inner tube could only be used with that form. But this inner tube, again, disappeared from the world of surgery until about 1853, when it was re-invented and adapted to the curved canula by Obre, (23) a London surgeon. This inventor first made it project slightly internally beyond the outer tube, thus gaining the maximum of efficiency for keeping the passage clear of mucus.

That royal but almost untrodden road to tracheotomy, the tracheotome, received some attention during this period. Richter improved on the instrument of Dekker, and debated the practicability of using it. A. Louis also discussed the question, and gave the first noticed account of a tracheotome invented in 1746 by a French surgeon named Bauchot. This instrument consisted of a lancet-shaped knife with a stout handle sheathed in a flattened canula; and also of a crescent-like blade designed to fit over and steady the trachea during perforation. Bauchot is said to have used his invention successfully in two cases. (24) Again, in 1853, Sir H. Thompson devised another tracheotome, a bivalve lancet, the two laminae of which are held together by a screw that causes them to separate widely after entering the windpipe, so that a tube can be inserted.

(3) The right of Albers to be regarded as author of the pioneer work may, perhaps, be disputed by that of W. H. Porter, surgeon to the Meath Hospital, Dublin (entitled "Observations on the Surgical Pathology of the Larynx and Trachea," 1838), but although a very progressive treatise its comprehensiveness is too limited to give it a full claim to the first place.

(14) He published a summary of his paper in the Dictionnaire des Sciences Médicales, T. xviii, p. 505, Paris. 1817; but it was first printed in extenso in the *Nouveau Journal de Médecine*, T. iv, p. 3, 1819.

(15) Bichat in 1802 had alluded to the special liability of the larynx to oedema, but in too curt and casual a way to obtain for the disease a place in nosology. He stated that the larynx was subject to a "kind of serous engorgement" which occurred nowhere else, and "often suffocated the patient in a short time." He allowed that previous authors had described the symptoms, but affirmed that they were ignorant of the anatomical lesion. He tried experiments on dogs, with success, to produce oedema by injuring the larynx.—*Traité d'Anatomie Descriptive*, Paris, 1801-3, T. II, p. 396, 404.

## THE SURGICAL AND ETHICAL ASPECTS OF THE CASE OF GANGRENE OF THE HAND.

A REPLY TO THE REMARKS OF DRS. MOLONY AND RUSSELL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I must in the first place take exception to the term *land-bill* as applied to the record of the case previously published by me. That publication was in strict medical form, and obtained very much less lay circulation than many of the reprints from medical journals do. I shall say nothing of your introductions, but waiving those precedents altogether, I say that medical etiquette disentitles no man to defend himself, even if he be obliged in so doing, to appeal directly to some of the laity, in order to disabuse their minds of misrepresentations with which they may have been previously infected. It would have been of very little use for me, or for any other aggrieved member of the profession, to appeal to one of the high-sounding colleges

to punish a delinquent. The journals are weekly full of the inutility of such applications. I might have sent my communication in the first instance to a medical paper, but if such were subsequently put into the hands of some of the laity, in what would consist the difference? Yet, from the moment of the publication of your issue of July 22nd., that was the course adopted with numbers of that issue by those two medical purists. It would be too painful to me to dwell minutely on the course adopted by those two gentlemen; let it suffice that the truth should be made known, and that, with that object it should be put within the public reach.

In the second place, I feel constrained to reiterate every single one of the statements made by me in my previous article. I decline to recognise snipping off a remnant of skin as in any way invalidating the statement that the hand dropped off. Further, it is wanting in ingenuousness to state that the portion of the arm corresponding to the compress subsequently sloughed almost to the bone, the full facts being that after cellulitis, which involved the entire extremity, extensive sloughing took place in several parts of the arm and forearm, and amongst them in this part. It is not the fact that the bandage and compress were literally buried in the middle third of the arm, nor is it the fact that Drs. Moloney and Russell expressed doubts as to the possibility of saving the hand, but on the contrary, they proclaimed to town and country, (such is *their* love for professional etiquette) that they would save it to the very nail; and they utterly scoffed at the existence of gangrene.

Lastly, I deny that I proposed to amputate at the shoulder-joint. On the contrary, I left the exact point to be determined, when the precise vessels injured would be ascertained under ether. I may, however, have expressed the belief that the seat of injury would be found to be the proper point, and to that I adhere.

This patient subsequently required the attendance twice a day for nearly three months, of an army of medical attendants, together with trained and untrained surgical helps. He suffered, as I have stated, from blood-poisoning, and has been more than once at death's door, and would at this moment convey to us a more accurate appreciation of the precise value of the stump left, if we had a report as to its actual state from some outside surgeon.

From all these it will be easily seen how much better it would have been for the patient had these gentlemen promptly recognised the gangrene, and had amputation been performed in time to prevent the consequences that subsequently ensued.

I now come to the charges of my honourable *confères*, and the first thing to be noted in connection with them is that they have now shifted their ground. The first time, one of them alleged it was by digital compression the case ought to have been treated; while No. 2 contented himself with alleging that the bandage ought to have been applied from the fingers. When, at length, both were constrained to admit the presence of gangrene they charged my treatment with being responsible for it. Now, I am charged with unsurgical treatment for putting on a bandage at all, instead of cutting down then and there on the wounded vessel or vessels, and tying their ends. Letters are produced from six gentlemen containing replies to an evident leading question, and enunciating a surgical rule which, however abstract in itself, does from its position in the context clearly lay down the dogma that I was not at liberty to treat my case by any other means than that of operating on the spot by cutting down on the ends of the vessels and tying them. Now, I will assume for the sake of argument that this is the meaning to be attached to the letters of those six gentlemen; I will at once join issue with their contention, and for that purpose will now quote the surgical rules in their entirety, and not after an incomplete fashion, and from writers which the most respectable of those gentlemen must acknowledge to be the authorities on the subject.

Mr. Erichsen says (p. 155) that the rule of surgical practice is to cut down directly on wounded vessels, *where it is proposed to treat them by ligature* and to tie both ends. But this rule is neither absolute nor universal, as will be seen from the following quotation from the same work. It will be found in page 157. It is as follows:—"No operation should be undertaken, unless the bleeding be actually continuing. If the bleeding have been arrested, however furious it may have been, the surgeon should never go in search of the wounded vessel, or undertake any operation

unless it burst forth again. A man was brought to the University College Hospital with a deep stab in the groin, directly in the course of the external iliac artery; a very large quantity of arterial blood had been lost, but the hæmorrhage was arrested on his admission by the application of pressure. From the great and sudden loss of blood it was supposed that the external iliac had been punctured; but it was not thought advisable to perform any operation unless hæmorrhage recurred. The bleeding did not return, the wound healing without any further trouble. In secondary hæmorrhage the case is different. There, the vessel must be secured, even though the bleeding has for the time ceased."

The foregoing quotation determines two things: 1st. That a choice of procedure is at least open to a surgeon; and 2nd. That pressure over the part is all that is called for; for there is not one word here about this case of wounded femoral artery being bandaged from the toes up. The plain meaning of the words would entitle me to go much farther; but enough for my purpose if it is minimised so as to cover the right to exercise a choice in the matter. Further on, the same writer states: "In primary hæmorrhage" (th t now under consideration) "the rule of practice is not to interfere by operation if once the hæmorrhage has been arrested by other means." So much for Mr. Erichsen.

Now, for Mr. Moore, Surgeon to the Middlesex Hospital. In an article on the treatment of wounded vessels, after quoting from the practice of the great military surgeons, he sums up, and declares the rule generally followed by surgeons to be no operation in early and doubtful cases, but reliance on pressure, cold, &c.

Again, the *Lancet* of July 18th, contains a review of a paper by Dr. Stimson, of New York, which comes to the support, if such were needed, of the views of the preceding writers. Here is what Dr. Stimson has to say. He tells us that he has ransacked the pages of medical literature for all the cases of ruptured axillary artery, and that he finds them to be forty-four in number, and that out of these, eight cases, and eight cases only, were treated in accordance with the surgical rule of applying a ligature to both ends of the vessels, and that in every single one of those eight cases death ensued. He goes on to enumerate the various measures adopted for the treatment of the remaining thirty-six cases, and, as the outcome advocates pressure as the safest. He advises this to be conducted by means of a pad and tight bandage over the injured vessel, and over it alone, there not being one word about those finger bandages, the necessity for which will, no doubt, now become apparent to our American cousins, when they shall have had time to digest the communication of my honourable confrères. Finally, the *Lancet* endorses the views of the distinguished American surgeon.

The practice of Charing Cross is clearly shown by Mr. Bellamy's case in the *Lancet* to be the same. Here I may observe that, though it was the ulnar artery that was wounded in his case, yet when the pressure treatment was employed, there was no proof that the injured vessel was not the brachial, and hence the practice of that hospital is identical with mine. An attempt has been made to make out that Mr. Bellamy's opinion does not cover my case also. I have a letter in which he declares that it covers both. I mention this to prevent any misunderstanding as to his views on the subject. To cut down on a vessel, in order to ligature its ends, has more than once led to the instant death of the patient, and the surgeon has still oftener failed to find the ends. Under such circumstances I adopted the course which was most conducive to the interests of the patient, and I at least saved his life, even though I failed to preserve his limb entire. Gangrene is no unusual accompaniment of grave arterial wounds, attended by extreme loss of blood. It is one of the accidents after ligature which is distinctly set down in our text-books; and, I believed it would have ensued in this case under any line of treatment. I believe it was due in this instance to two well-known factors, viz., to aortic obstructive disease, and to the extreme exsanguined condition of the patient. On more than one occasion, I detected an aortic murmur which had all the characters of an organic one.

After the appearance of the communication of July 22nd, I addressed a letter to each of the six gentlemen, calling his attention to the article contained therein, and inquiring whether his letter was intended to convey that the treatment pursued by me in the case referred to was contrary to sound surgery. To this I received the following replies:—

1. From Dr. Hamilton.—"In my letter I expressed no opinion on your treatment."

2. From Dr. Pearson.—"My observations referred to the abstract question only, and I would not venture an opinion on a given case without seeing it."

3. From Dr. Jones.—"I did not mean my letter, which was published without my knowledge to bear on any special case."

The two following will strike most people as very curious replies:—

4. From Dr. Ormsby.—"Pray, excuse my not entering into a correspondence concerning a subject, the merits of which I am not acquainted with."

5. From Dr. Watson.—"Dear Sir,—In reply to your letter of the 19th inst., which only reached me to-day, I can only say that I am in absolute ignorance of all the circumstances to which you allude.—Yours faithfully, PATRICK HERON WATSON, Edinburgh."

Here is an extraordinary state of things. Two gentlemen come forward to offer opinions on a case, the circumstances of which, they tell us, they are wholly ignorant of. I may surely leave these letters to speak for themselves. Now I come to Dr. Ireland Wheeler:—

"Dear Sir,—I am in receipt of your letter. I have not a copy of the medical journal you refer to by me, but I am certain that I expressed myself clearly, and that whatever I have written cannot be misunderstood.—Yours faithfully, W. I. WHEELER."

As his letters are anything but clear, I now call on Dr. Wheeler to state explicitly whether his first letter is intended to convey that the treatment pursued by me in the case quoted was or was not, contrary to good surgery. I am quite aware that, unlike the gentlemen from Cashel, most certainly not tyros, he is careful to lay down no garbled surgical rules, but is modestly content to state what he himself would do in the case of a wounded artery, viz., tie both ends of the vessel. He is further cautious in the matter of bandaging the fingers; for he tells us that in venous hæmorrhage he would do so, a condition of things outside the case altogether. Nevertheless, the appearance of this gentleman's letter in the company in which it figures gives to it one meaning, and one meaning alone, viz., condemnation of my treatment. I again call on him to leave no room for doubt or misunderstanding by enunciating this in plain English. In such event we shall have Dr. W. I. Wheeler on one side and Mr. Erichsen, Mr. Moore, Mr. Bellamy, Professor Stimson, and a host of others on the opposite side.

I am, Sir, yours, &c.,

The Union Hospital, Cashel. THOMAS LAFFAN,

[We have given Dr. Laffan the opportunity for reply, but as any surgical interest which the case may have had is already exhausted, and as we have given our strong opinion against Dr. Laffan on the ethical aspect of his handbill publication, we do not propose to continue the publication of any further communications on the subject.—ED.]

## Clinical Records.

### CASE OF BELLADONNA POISONING DURING PARTURITION—RECOVERY.

By ALFRED S. GUBB, L.R.C.P., M.R.C.S.

A WOMAN, æt. 32, about to be confined of her third child, was attended by the village midwife, and as the labour was very tedious the midwife, who acted to some extent as the representative of the local medical man, sent a bottle to the surgery for some ergot. The doctor gave the bottle to his assistant simply telling him to fill it. The latter not knowing what the bottle had contained, smelled it and recognised the odour of liniment of belladonna, which he therefore dispensed, not, however, omitting to protect it with a poison label. The midwife on receiving the bottle promptly administered a teaspoonful of its contents, followed soon after by a second. In the course of two hours, however, she became alarmed at the "carryings on" of her patient, who rolled about on the floor, throwing her arms about and talked incoherently and indistinctly. There was some sickness, but the patient gradually became comatose and only muttered unintelligibly when spoken to loudly or shaken. The doctor was sent for and when he arrived the patient was quite inert, unable to

stand or reply to any questions, though she still mumbled something when moved on to the bed. As sickness had occurred, and as some time had now elapsed since the administration of the poison, the doctor did not deem it desirable to do anything further to counteract its effects and she was simply placed on the bed and allowed to sleep. On examination, the head was found low down on the perineum, the forceps were then applied, and delivery effected without difficulty, the placenta following in due course, and with no hæmorrhage. The woman gave no signs of pain during these proceedings, and continued to sleep on for several hours. Ultimately she awoke, and was much astonished on being told that the child was born, having no recollection of what had taken place. She said she felt "dazed," and complained of the dryness of the mouth and throat, also of "weakness," especially in the legs. Her speech was difficult and indistinct, probably from the dryness of the mouth. The symptoms gradually passed off, and she made an excellent recovery without any further difficulty.

### Department of Lunacy.

#### PSYCHOLOGICAL SECTION OF BRITISH MEDICAL ASSOCIATION AT CARDIFF.

IN Dr. Yellowlees the Section had a stirring and lively President no less than an excellent speaker and an experienced psychologist. The subject of his address was a great one even if it has been worn threadbare of late; but we fear he brought little that was new to bear upon its problems, and it savoured rather of an address to a public audience than of a display of thoughts worthy the digestion of medical men. The causes and prevention of insanity are so exceedingly numerous and complicated, so involved one with another, and in many cases so far from the reach of scientific estimate that we should have preferred to see Dr. Yellowlees laying down the law with greater reserve, and not allowing lugubrious reflections to find expression till he had tested their foundations in the light of careful calculation and scientific accuracy. The physiological action of alcohol does not seem to have been sufficiently considered in the calculation which Dr. Yellowlees made of the effects of "nips," "night-caps," &c., on the future of the individual or his posterity. What real ground has he for his sweeping generalisations as to the future and the posterity of the drinking population of the country? What reliable data can he bring forward to support his imputation? As a result of investigation under the least complicated conditions, the sum of our certain knowledge of the physiological and pathological action of alcohol is too meagre for such a fell swoop as Dr. Yellowlees deluged his hearers with. Moreover, in reference to brain exhaustion from sexual excesses and self-pollution, we think the President might have found a theme in itself sufficient to do bare justice to in the space of a single address; but he discusses it in a paragraph, and we are again forced to think he is too rough and ready in his estimates. The relations and the reaction of the sexual paroxysm and nerve energy on each other are still too little understood for us to say that unbridled indulgence in sexual intercourse within the marriage state "may wreck the strongest brain." A great many "strongest brains" and average brains too are not yet wrecked after something more than unbridled connubial intercourse. If he is right, the relative proportions of our sane and insane populations will be reversed in a century. While we have said so much in disparagement of some of Dr. Yellowlees' conclusions, there are others which we have felt to be wise, sound, and well-timed, and we especially commend the observations on self-control, moderation in all things, and a graduated system of education conceived in a physiological spirit. The address as a literary effort was

very fine; but we must again express our opinion adversely (as we did last year regarding Dr. Savage's) to addresses of this kind. They are formal, expansive, and ornamental, rather than useful. If we are to have new and valuable truths, we ought at least to have a share of them from the Presidents of Sections. Dr. Yellowlees has a ripe experience, and he has the gift of speech in a rare degree. Could he not have selected a smaller subject, and disclosed some new and curious truths worthy to claim a page on the history of science?

#### THE TREATMENT OF MANIACAL EXCITEMENT.

The discussion on this subject, ably led off by Dr. Campbell, of Carlisle, was vigorous, animated, and at times heated. The old forces of restraint and non-restraint, chemical restraint, &c., were ranged in opposition, and the conclusions arrived at were far from being unanimous, albeit Dr. Campbell had endeavoured by classification of maniacal excitement to lay down a definite basis of debate, the speakers soon kicked over the traces, as is too often done, and hopeless irrelevancy was too frequently the rule.

#### LUNACY LEGISLATION.

Dr. Hack Tuke read a clever paper on this subject, but treated of it in a manner described by the President as happily irrelevant. Dr. Tuke makes a strong demand for more Commissioners, he advocates State aid or local help to registered hospitals, and he claims for medical men that they should be safeguarded from undue interference by the magistrate when providing lunacy certificates.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 26, 1886.

#### WILL THE CONGRESS MEET IN AMERICA?

It would be idle to attempt concealment of the fact that not only is the success of the proposed meeting of the International Medical Congress at Washington imperilled by existing dissensions in the profession of America, but that it is a serious question whether the gathering can be permitted to be held there at all. We are alive to the possibility that the curious arrange-

ments entered into by the clique of the American Medical Association may be fully carried out; but at the same time we are perfectly certain that a congress convened under such circumstances will not be international in any sense of the word, but will develop into nothing more imposing than a magnified mutual admiration society. There is no longer any doubt that all the leading members of the profession in America will at such a gathering be conspicuous by absence, or that European practitioners will fail to find any recompense for this fact in receiving attentions from gentlemen whose names they are unable to associate with the extension or perfection of scientific knowledge or the advancement of the art of medicine. Three thousand miles and more is a lengthy journey to make merely for the sake of a friendly hand grasp and the interchange of courteous platitudes, though there are not a few among the deposed officers of the Congress for the sake of seeing whom we would, personally, gladly make such a pilgrimage. It is, however, the conviction that even a brief spell of converse with these eminent men would profit us extremely, that animates the thought to which expression is given above; while we cannot stir up any equivalent enthusiasm in reflecting on the probable advantages to be derived from similar intercourse with the, no doubt, excellent persons who have elected themselves into posts that can only fittingly be occupied by physicians of recognised ability and genius.

The whole history of the International Congress has nothing so unfortunate as this episode to show, and we are deeply grieved that a great country like America, a country that is closely united to us by the holiest ties of blood and community of thought, should be the first to stir the deep waters of science by the introduction of a miserable and unworthy quarrel about—*ethics* forsooth! In truth it is a mean and miserable bone that is the cause of contention. What is it to the sacred light of science whether its followers are members of this, that, or the other Association? and who outside the arena of local politics will care a straw for the ethical opinions of men with whom he is associated in common pursuit of a great and honourable profession? We want to meet the doctors of all nations at an international congress; and so that they be doctors and honest men, what other right or title to be present need they have? Possibly, nay even probably, such catholic invitations as the Congress naturally extends may give admission to a few whose claims to be regarded as doctors *and* honest might be open to criticism; but even so, let them come; they cannot but be benefited and instructed; and who that loves his calling will not join us in the cry. It is perhaps unfortunate that the absence of any uniform law in America to which every practitioner must conform, has rendered such a plea necessary in connection with the coming Congress; but let this shortcoming be admitted as it should, and its drawbacks be discounted in advance.

At the present time the situation is this. The American Medical Association has taken into its hands the regulation of the Congress, and has decided that only those practitioners who are in membership with it, or not being members are delegated by medical societies and recognised by it in this

connection, shall be admitted to the Congress. It has further *revised* the list of appointments made by the original committee appointed at the Copenhagen Congress, and replaced many of the names therein with others of its own choosing. Result: Almost every physician of standing has declined to accept the office assigned to him, and the list as now constituted is, at any rate to those on this side of the Atlantic, one of the most ludicrous productions of recent times.

Is it not time for an end to be put to this anomalous state of things? We here in Britain are jealous of the honour of the profession in America almost as much as for ourselves. We cannot but regard our American brethren as forming with us a single united body, and its prestige is dear to us as our own. One suffers with the other, indirectly, and we here will not, if we can prevent it, be pointed at by neighbouring nations as incapable of united action for the common good. Let those who are responsible for the present trouble in America acknowledge their mistake and amend it. Now it is possible; later it may not be.

#### THE BRADSHAW LECTURE.

ON Tuesday, the 21st inst., the annual Bradshawe lecture at the Royal College of Physicians was delivered by Dr. Goodhart, of Guy's Hospital, who occupied his distinguished position under somewhat mournful circumstances. The duty was to have been undertaken on this occasion by the late Dr. Mahomed, whose early death at the close of last year created such widespread regret throughout the whole profession; and in selecting for the subject of his discourse that of arterial tension, Dr. Goodhart responded to a warm and graceful feeling dictated by his long friendship with one who was almost up to the day of his death engaged on the study of this particular question. The personal testimony borne to the character of Mahomed by Dr. Goodhart is eminently deserved, and the few words in which the lecturer formulated the estimate in which his departed colleague will be held will be accepted as a faithful tribute to his worth.

Dr. Goodhart wisely elected to put his address in the form of a critical review of the received explanations of morbid arterial tension, and the result is a careful and masterly, impartial discussion of the pathological and clinical data on which the contending theories are based. He clearly showed that the present is incapable of affording demonstrable evidence on either side, but that the hypothesis of arterio-capillary degeneration, the "arterio-capillary fibrosis" of Gull and Sutton, is more worthy of acceptance than Dr. Johnson's well-known theory of spasmodic arterial contraction. In a somewhat more definite manner than usual, perhaps, he inclined also to accept the occurrence of functional disease apart from evident structural changes, but he was careful to imply that molecular alterations, inappreciable to such means of observation as are yet available, very probably precede such functional affections. The association of the relations of renal to general disease received some consideration, and a brief space was devoted to the question of the production of dilatation of the pulmonary artery without other signs of serious

disease. The lecture was of the most scholarly character throughout, and was listened to with rapt attention by an unusually full audience.

#### MEDICAL MEN AS VOTERS.

THE adhesion of the average commonplace voter to one or other political party is a sort of fetish which binds him to shibboleth which, generally speaking, has for him no meaning. This class of voter supports with great enthusiasm one or other candidate, and delights to fuss about as an ardent politician, and to take a leading hand in the little local political game when the play is going on. But, generally speaking, he cares nothing for the candidate; has the vaguest idea what his opinions are; does not even know with any accuracy what the policy of "the party" may be; and has no better reason for all this political enthusiasm than the fact that he has got his politics out and dry from his father and grandfather, and likes to be with the "respectable party" or the "go-ahead party" as the case may be. This sort of voter never seems to remember that his own vote and influence is the most homœopathic quantity in the calculation of his candidate's chances; that, as regards the general policy of Government, the votes of thousands like him is of no influence or practical effect whatever. If he be a medical man he also knows that he has nothing whatever in the way of consideration, attention, or favour to expect from any party, and that it is almost totally indifferent to him either from a political or a medical point of view who sits on the Treasury bench.

Why, then, will medical voters insist on blindly following the whistle of political wire-pullers when, by throwing their influence into the scale with medical interests, they could exercise a material influence and give valuable help in furtherance of needful medical legislation? We affirm that, as a universal rule, a medical voter should vote for a medical candidate, no matter what his politics may be, and that, if there be no medical candidate for his constituency, he should vote for that candidate who would give the most satisfactory pledges on medical questions.

On this principle we join the *British Medical Journal* in advocating the claims of Mr. Eric Erichsen. He is a candidate who, by his professional and social position, by the high rank which he occupies in science, by the power of intellect and energy of purpose of which he has given abundant proof, is entitled to confidence and support on his own merits. Whether, if he should get into Parliament, he is going to vote for protection or free trade, for the occupation of the Soudan or for the building of torpedo boats, we do not care a straw. We know he will make a brilliant representative of medical affairs, that he will be able to form a sound judgment on medico-educational reform, on lunacy law, on sanitary legislation, and other cognate matters, and in this view we think that the medical voters of the Universities of Edinburgh and Aberdeen will be very foolish if they throw their votes into the vortex of general politics and thus efface their influence in the constituency.

There may, of course, be instances in which a medical candidate forfeits his claim to the support of the profession by sacrificing his principles, descending to disreput-

able political dodgery, and buying the support of anti-contagious diseases fanatics, anti-vaccinators, anti-vivisectionists, and quacks by means of pre-election pledges. Such a claimant deserves to be repudiated as a representative of medical men, and has no right to expect any support whatever; but he is, we hope and believe, a rare exception, and proves the general rule that the doctor should, in politics, be a doctor first and a party man afterwards.

#### Notes on Current Topics.

##### The Marseilles Epidemic.

AT the French Academy of Medicine on the 18th inst. a letter was read from Dr. Solari, of Marseilles, in which the writer protested against certain assertions made by Dr. Brouardel respecting the local origin of the cholera epidemic in that town. Dr. Solari insists that the disease was imported last year from Tonkin, and that its introduction occurred through the transport vessel *Sarthe*; moreover, he asserts that in the Tonkin delta cholera is endemic, and that its transmission to France was the principal result of the conquest achieved by the latter country. Dr. Solari also considers it to be the duty of his Government to purchase one of the Levantine islands and employ it as a station for the temporary sojourn of suspected persons returning from Tonkin. To these statements Dr. Brouardel replied that there was absolutely no proof that the *Sarthe* had been the means of introducing the disease into France; and against the delta epidemic theory he urged that cholera foci were more often discovered inland and along the banks of the Gauges than in the delta properly so-called. This controversy is not likely to be speedily terminated; and meanwhile the municipal authorities of Marseilles are at last showing an earnest desire to place the town in something approaching a condition of health, a result which must after all be regarded as the most satisfactory outcome of the terrible lesson taught by the loss of life inflicted on its inhabitants.

##### A Hotbed of Germs.

A LIVERPOOL paper has been the means of drawing public attention to one of the worst instances of carelessness in respect to the public health that has ever been exposed, and which reflects the greatest discredit on all those who are responsible for permitting it to exist and continue. It appears that in a part of the city known as West Derby there is situated in the midst of a closely populated neighbourhood a disused quarry, into which it has been customary for all kinds of filthy rubbish, and every kind of abomination, to be "shot." The consequences of such heedless negligence of every sanitary rule can easily be imagined. Affording a convenient place of deposit, this hole has received a ceaseless succession of cartloads of refuse too offensive to rank as "rubbish" even, and has thus been stocked with material in which the germs of disease can find abundant means of development, and whence at all times must emanate the most sickly, even though they chance not to be deadly, odours. As a consequence, sickness, attributed by the unfortunate residents near by to the decomposing heap,

is always more or less prevalent, and has led to complaints on several occasions and to the interference of the medical officer of health for the district. This gentleman's representations, however, have been ineffectual to prevent the continuation of the nuisance, and now it remains to be seen if the authorities can be roused by other means to a sense of the injury their inaction is producing. They have ample powers to put a stop to the offence committed by those who are immediately responsible for it, and it will be well for Liverpool if this is accomplished ere the ravages of an epidemic disease proclaim that the laws of health may not be violated with impunity.

#### A Timely Warning.

DR. SKEGG, medical officer of health for the district of St. Martin-in-the-Fields, applied to Mr. Flowers, at Bow Street Police Court, on Saturday last, for an order against the proprietors of certain tenements in White Hart Street, requiring them to close the dwellings as unfit for human habitation. The premises consist of 51 rooms, and are planned without any sufficient regard to the necessities of their occupants. The rooms are described as being very small, and as being kept in the most filthy state, Dr. Skegg characterising their condition as "pestilential." The most distressing feature about the case, however, is that a very inadequate water supply has been provided, scarcely enough for ordinary drinking purposes being obtainable, while cleanliness and the needs of health in this connection do not appear to have been considered in the arrangements. Complaints made to the owners of the property have proved quite unavailing, and hence Dr. Skegg has very properly proceeded to the extreme step of soliciting the magistrate's order to close the premises; and it is satisfactory enough for ordinary drinking purposes to run any risk such as is involved by the presence in our midst of unsanitary buildings; and every encouragement rather should be given to the poorer inhabitants of cities and towns to promote their own and their neighbours' health by giving them surroundings that will not at any rate favour the production and spread of disease in their midst.

#### The Centenary of Digitalis.

DR. W. MURRELL, under the heading "The Centenary of Digitalis," has contributed to a contemporary an exceedingly interesting letter descriptive of the first introduction into regular medical practice of digitalis as a remedy for dropsy. It is, he says, just a hundred years since a Birmingham physician, Dr. William Withering, after ten years' experience of the drug, published his "Account of the Foxglove and some of its medical uses." His acquaintance with the plant in this connection commenced through his being called on to pronounce as to the value of a mixture made by an old woman in Shropshire, and which was said to have cured dropsy in many

cases treated unsuccessfully by physicians. Dr. Withering found that out of the twenty ingredients of the mixture only one, and that digitalis, possessed any real therapeutic virtue. He accordingly employed it himself, and induced others to make trial of it, but his views, as has been the case with most important improvements in medicine, met with much active opposition. His prophæcy that "in spite of opinion, prejudice, or error, time will fix the real value upon this discovery, and determine whether I have imposed upon myself and others, or contributed to the benefit of science and mankind" has been most amply fulfilled; and at this period of time, when the drug is universally employed by medical men for the treatment of certain forms of disease, it is interesting to be recalled to a memory of the early trials attending its introduction to the *materia medica*.

#### The German Association of Naturalists and Physicians.

THE fifty-eighth Congress of German Naturalists and Physicians is fixed to take place at Strasburg, and will commence on Thursday, September 17th next, and terminate on the 23rd of the same month. Notices of communications and abstracts of papers must be forwarded to Herr J. Stilling.

#### An Exhibition of Criminal Anthropology.

THE Anthropological Congress which is shortly to be held at Rome will, says *Nature*, have a curious feature in a collection of seven hundred skulls of criminals, numbered and classified. To these will be added the photographs of 3,000, and the brains of more than 150 convicts, thousands of autographs, poems, sketches, and special instruments, the work of criminals, an album containing a record of 700 observations, physical and moral, on 500 criminals and on 300 ordinary men. There will also be graphic maps of crime in Europe with reference to meteorology, food, institutions, suicide, &c.; tables of the stature of criminals in relation to the length of the arms, and of crime in towns compared to that in the country. M. Bertillon will exhibit the graphic curves of 23,000 *recidivistes* examined in twelve parts of the body, and the practical results obtained. Photographs of Russian political and other criminals, especially of those from Moscow, and wax masks of a large number of celebrated criminals, will also be exhibited. All the notabilities in the science of criminal anthropology will take part in the Congress.

#### Galvano-Puncture in a Case of Aneurism.

IN the *Rivista Internat.* Dr. Brancaccio relates a case of aneurism of the ascending aorta very much relieved by galvano-puncture. There was no previous history of any value except that of alcoholism. The tumour projected about an inch in the infra-clavicular region, and was bounded above by the upper border of the second rib, to the left by the mammary line, to the right by the sternum, whilst below it merged into the cardiac dulness. The heart was healthy, the radial pulse small and occasionally intermittent, was synchronous with the beat of the heart. Severe pain in the chest, cough and dyspnoea were present. Daniell's battery, consisting of fifteen elements, was employed. Two

strong steel needles were plunged 3 cm. deep, 4 cm. from each other, in the third intercostal space. The left needle was connected with the positive pole, the right with the negative. The operation lasted sixteen minutes. Dr. B. saw the patient ten hours after: the pain had then disappeared, respiration was normal, the swelling diminished, the pulse from 118 had fallen to 90, altogether he was stronger and better. The second operation took place twenty days later, the number of elements being increased to twenty. Severe pain, rigors, pyrexia followed, but soon passed away. The operator thought fit, however, to lessen the number of elements to fifteen at the third and fourth operations. Eight weeks after the last operation the patient left the hospital at his own desire. His general condition was much improved. The cardiac pain had disappeared, the tumour was smaller by at least an inch, the cardiac impulse was more powerful, the pulse more regular, fuller, and stronger. The author recommends galvano-puncture for small aneurisms which have not extensive communication with the artery. The case proves at the same time that the situation of an aneurism just above the aortic valves is no contra-indication to the use of galvano-puncture, as several authors have stated, thinking that the difficulties of clot formation in that situation were insuperable.

#### Systematic Examination of Wet-Nurses for Preventing the Transmission of Syphilis.

SEVERAL years ago a bureau was started in Moscow where wet-nurses could be examined by specialists with reference to old or recent syphilis. The examination was intended to be a very searching one, on account of the latency which characterises this disease, and the possibility of further outbreaks in such cases. A certificate of immunity was withheld if suspicious glandular swellings, scars in certain places and of a certain character, suspicious pigmentations, or swellings of the bones were present, or if there was a history of repeated miscarriages. The condition of the nipples was especially noted. Of 490 women who were examined in the course of three years, seventeen per cent. were refused certificates of immunity. In an additional four per cent. of cases, the evidences of syphilis were unmistakable. It is gratifying to know that this bureau appears to have met with the approval of Russian physicians. But in our country the establishment of such an institution is hardly practicable.

#### Accouchement by Firearms.

A STORY is going the round of our French exchanges, on the authority of M. Granier, surgeon in the French Army, in Algeria, that at Brizerte, where the military authorities had recently forbidden, under the severest penalties, the discharge of firearms within the town, the whole garrison was awakened at three o'clock one morning by the tremendous explosion of a heavily loaded gun in the neighbourhood of the ramparts: a guard of soldiers rushed into the house from whence the sound had come and found a woman lying on the floor, with a newly-born babe between her thighs. The father of the child stood over his wife with the smoking musket still in his hand, but his intentions in firing; the gun had been

wholly medical, and not hostile to the French troops. The husband having discovered that his wife had been in labour for thirty-six hours, he thought it advisable to provoke speedy release for her, and, following the Algerian custom to *scare the baby* out, he had fired the musket near his wife's ear; instantaneously the accouchement was terminated.

#### The Army Medical Competitive.

WE published last week the list of the candidates for army and naval commissions at the last examination at Burlington House. We understand that 85 candidates presented themselves for 30 army vacancies and 16 commissions in the navy. Of the 85 candidates, 35 were educated in Ireland, of whom 7 obtained appointments, including Mr. Yare, who took first place. Thus at two successive competitions the first place was taken by Irishmen, Mr. Hickson being the best man last February. The first place in the Indian Service was obtained by Mr. Granger.

WE publish elsewhere the papers on Medicine and Surgery, and hope to find place for the other papers next week. Mr. Pollock's paper on surgery is in all respects a fair practical test of knowledge, such as a sufficiently educated surgeon ought to be able to answer, but an ignorant or stupid candidate could not deal with. Dr. Aitken's paper on medicine is, in some respects, a model of what an examination paper ought not to be. The first two questions demand from the candidate an "analysis and commentary" on two cases which are given in detail and occupy three closely-printed pages. The necessary reading of these cases two or three times over to enable the candidate to understand them would of itself consume a good part of his available time, and the quantity of detail of signs and symptoms which is packed into them is enough to extinguish the diagnosing faculty of even the smartest student. Worse than this, the first subject of question is a 70-line narrative of a case of intra-thoracic sarcoma, which, after half-a-dozenappings, incisions into chest, and applications of drainage-tubes, died unrelieved, leaving the surgeons in a quandary which was solved only by post-mortem examination. The unhappy competitor was expected to diagnose disease which the surgeons in charge failed to make out, and, having done so, he was required to "expound its pathology, state views as to the initiation, progress and development of the symptoms and physical signs, and their mutual relationship, and to describe the probable post-mortem appearances." The second question was a still more elaborately detailed case of myxœdema, needing for its answering the astuteness and experience of Sir Thomas Watson and the literary facility of the editor of the *Times*. The remaining questions on the paper are fair tests, but, as a whole, the paper is such as to justify our recent criticisms upon the system of competitive examination for the Services, and our conclusion that, in many respects, they are anything but a fair criterion of the erudition or practical efficiency of the competitor.

DR. LOMBE ATTHILL, of Dublin, has been elected a corresponding member of the Gynæcological Society of Boston, U.S.

### The Social Evil Movement.

A NUMBER of well-intentioned people met in conference at St. James's Hall on Friday last to discuss and pass resolutions to repress the social evil, but which, as Lord Lynton reminded the meeting, if not most carefully handled, would be sure to do more harm than good, by driving the evil deeper in, and multiply the crimes they were intended to repress. That it has been so already is evinced by the extraordinary admission of a Mrs. Josephine Butler. This lady confessed that she and her friends have intentionally bribed others to enter into immoral contract with regard to young girls whom all the time they intended to protect from evil, and did protect from evil. The Editor of the *Spectator*, in expressing his unqualified disapproval of the proceedings, says: "In this case this lady and her friends have tempted by their proposals to the worst act that a human being can commit, and they may never be able even to prove to the person so tempted that the intention was not what it appeared to be. Even if they can, they can never undo the assent which they invited another to give to a frightful wickedness." The Bishop of St. David's, in answer to the invitation of those who summoned the conference, said: "I am sure I shall not be regarded as indifferent to the object which the promoters have in view when I say that I am unable to accept the position thus conferred upon me, partly because I am unwilling by accepting it to be supposed to express indirect approval of the recent action of the *Pull Mall Gazette* (which I regard as perhaps the gravest offence against public decency and morality which has ever been committed in any even nominally Christian country), and partly because I do not think a public demonstration either desirable in connection with such a subject, or a promising mode of bringing about the end which the promoters have in view." We commend this view of the question to the leaders of the movement. The greater the publicity and agitation the more likely to promote the evil rather than repress or lessen it.

### Remedies for the Social Evil.

CONSIDERABLE differences of opinion arose at the St. James's Hall meeting as to the remedy for the social evils of large town. One speaker warmly espoused the Malthusian doctrine, but this was scouted, and it ultimately fell to the lot of an unmarried lady, Miss Ellice Hopkins, to propound a perfect cure, and which seemed to be very acceptable to the ladies present. She argued, and with apparently a good deal of success, that in order to reduce the number of unmarried men, the heads of families should show more willingness to train and educate their daughters to become the wives of poor men. "They will," she said, "be much happier as the wives of poor men than not wives at all. Many single women are eating out their hearts because their parents have a comfortable ideal for them, which leads to the starvation of the heart, and is the hungriest part in a woman's nature." But among the divergent opinions advanced on this score, the following seemed to be the more acceptable:—1. That marriage should be encouraged as much as possible. 2. That it is better a woman should marry a poor man than that she should not marry at all.

3. That early marriages should be encouraged. 4. That the neo-Malthusians are rank heretics. 5. That employers should be compelled to discourage low wages.

### The Fifty-eighth Congress of German Naturalists and Physicians in Strasburg.

GREAT preparations are being made to render this Congress, the first meeting of which will take place on September 17th, a great success. It has never before been held in the newly-acquired provinces, so that a special and peculiar interest attaches to the occasion. Whatever unwillingness there may have been, when Strasburg was first selected as the place of meeting, on the part of *Alsatian savants* to welcome a German society, appears happily on reflection to have passed away. As is usual, English medical men may become members or participators under certain conditions. The fee for a member's or participator's ticket is 12 marks, the same fee entitling the holder of a ticket to one lady's ticket free. All the railways leading to Strasburg have been solicited to make concessions to members, &c., journeying to the Congress, and in most instances the concession has been granted. Any information will be given, and lodgings provided, on application to Herr Quastor Schmidt, Universitätsgebäude, Strasburg.

### The Berlin University.

THE Theological Professor Dr. Kleinert and the Gynaecologist Professor Gussacrow have been elected respectively Rector and Dean of the Medical Faculty for the year commencing October 15th.

On August 3rd was celebrated the 75th anniversary of the founding of the University. Amongst the ceremonies was a procession of students to the statue of the founder, King Friedrich Wilhelm III.

### Rearing Premature Infants.

SOME months ago we presented our readers with a series of illustrations and a descriptive notice of the "couveuse," a sort of incubator intended for the rearing of premature infants in artificial warmth. Prof. Tarnier recently presented at the Académie de Médecine two children born at the sixth month, whom he had succeeded in rearing by the aid of this apparatus and forcible feeding with woman's milk. Eight grammes of milk were injected through a caoutchouc tube into the stomach every hour for the first three days, and then sixteen grammes were injected every three hours. It is necessary to begin with small quantities, or the child becomes swollen by an acute œdema through hypernutrition. The couveuse is used at a temperature of 30° to 37° C. The younger the infant, the higher the temperature employed. Dr. Blot observed that he regarded the couveuse as a useless procedure, as the same results are attainable by the employment of cotton and bottles of hot water. M. Tarnier said that during the employment of the couveuse he had on several occasions been astonished at the rapid disappearance of the sclerema of infants.

### Outlawry of the Medical Practitioner.

MEDICAL students and practitioners are, we suppose from the irregular nature of their avocations, open to the accusation of being the worst possible people for answering business letters in a business-like way, and, as their success in life depends, in no little degree, upon their steadiness and punctuality in this respect, it would be very well for them to amend. In our columns to-day the Registrar of the General Medical Council appeals to the members of the profession to aid him and to protect themselves by answering the letters which he addresses to them before removing their names from the Register. There has, indeed, been much wailing by individual practitioners because they have temporarily lost their rights to recover fees by reason of the removal of their names from the Register, but one can have little pity for such grumblers, because they have incurred this penalty by neglect of the commonest precautions and the simplest civilities of life. The Registrar of the Medical Council *must* keep his Register as correct as possible by wiping out obsolete names and adding new registrars, and he is enjoined by Act of Parliament to make his corrections in the list by sending repeated letters to individuals who seem to have disappeared, and removing their names if they do not respond. If these practitioners receive letter after letter and will not answer even by a postcard, or if they leave their residences without making any arrangement about their letters, they have no right to expect that a public officer will halt in his duty to please them. We speak with experience, for we have in custody at this moment private letters and books addressed to persons who will not take the trouble to give instructions about them. For the benefit of practitioners of this class we beg to say that it will be the duty of the Registrar of the General Medical Council to remove from the Register every one of them who do not reply to his circular letter, that they will thereby lose their rights as practitioners, and that it will not be possible to reinstate them except after sufficient cause shown and with the express authority of the Council.

### A Royal Recognition of Devotion to Duty.

We have no little satisfaction in recording that Her Majesty has conferred the Albert medal upon Dr. Edward Thompson, Surgeon of the Tyrone County Infirmary, Omagh, in testimony of his courage and self-sacrifice in attempting to save the life of a child who was dying of diphtheria. The patient, Herbert Mitchell, *et. 6*, was admitted to the infirmary on the 4th April, suffering from a severe attack of diphtheritic croup, the tonsils being coated with thick white deposit, the glands of neck much swollen, and the other usual symptoms well developed. On admission he was moribund—so bad, indeed, that the consultants thought an operation useless, and went away. Dr. Thompson, however, thought he ought to give the poor child the faint chance of life which tracheotomy could afford, and therefore operated at once, but the moment the tube was inserted it became blocked, and the child ceased to breathe, upon which Dr. Thompson, without hesitation, cleared it by sucking it with his mouth. Even then respiration did not return, until the doctor, taking the inner tube between his lips,

kept up artificial respiration for a few moments, by which means breathing was restored. Unfortunately the child ultimately died, and Dr. Thompson was laid up with a bad throat for some days afterwards. The infection was also communicated to the matron, Miss Brownlow, who had nursed the poor child with entire disregard of her own danger, and she narrowly escaped death.

We have been obliged to press for the foregoing particulars, and the narrative is one truly honourable, not only to Dr. Thompson, but to our profession. We congratulate him on attaining a distinction to which his courage and self-sacrifice so eminently entitle him.

### The Pollution of the Thames and Lea.

THE present state of the rivers Thames and Lea are necessarily exciting alarm. They are most undoubtedly presenting cause for a good deal of uneasiness, if not alarm, just now, and the daily papers are flooded with correspondence on the subject. The condition of the Thames both above and below bridge is far from what it should be; indeed, the river between Blackwall and Erith (where indignation meetings have been held) is alarming and dangerous. Between these two points we have a floating population, estimated at about 25,000, and no plan has as yet been devised for dealing effectually with the sanitary requirements of so large a residential population, and scarcely varying in numbers or habits from one year to another. Then there is the outfall of the metropolitan sewage at Barking, which of course makes matters much worse. The Metropolitan Board is now, no doubt, doing its best to deodorise and render the effluent water less innocuous. But we learn that the process adopted is only attended with very partial success. The right to discharge the effluent water into the Thames has been given to the Board by statute, and it can only be called upon to do what it is advised to do by its engineer and those in whom it has confidence. But the difficulty of dealing with London sewage must be continually cropping up, since, as the monster city grows, it must pour more and more filth into its sewers, and which must find an outlet somewhere. Eventually it must be carried out to sea. The upper reaches of the Thames afford no better security against pollution and danger to health. The riparian population living on its banks are at a loss to know how to meet the difficulty or how to dispose of town ejecta. Sewage farming is declared to be a failure, and the several processes adopted for the precipitation of the grosser matters are scarcely ever to be trusted. The smaller tributaries of the river, the Wye just now, send into the stream not only the sewage of towns, but of numerous factories, and the refuse of unwholesome trades. The floating population living in hundreds of house-boats and pleasure-boats of all kinds, through the greater part of the summer months contaminate the Thames to a very large extent, and above the intake of the Water Companies. The river Lea just now is even in a worse condition. From a communication in a morning paper we find the total solids per gallon given at from 506 to 695 grains, inclusive of a high percentage of free ammonia and albuminoid ammonia. An analytical chemist to whom samples of the water taken from the Lea near the sewage works were submitted condemns the water as totally

unfit for consumption, from its excess of organic impurities, its disgusting smell, and the growth of sewage fungus, which constitutes a nuisance and a danger to health. It is incomprehensible to those thoroughly acquainted with the Thames and Lea that water drawn from such sources should ever be spoken of in terms of praise such as those usually employed by the chemists of the Water Companies. Fortunately London at this moment presents a clean bill of health, but we cannot shut our eyes to the fact that a former outbreak of cholera occurred at the East End of London, and which is far more densely crowded in every part than it was ten or twenty years ago.

THE Société Médicale des Hôpitaux has opened a subscription toward providing a bust of Dr. Noël Gueneau de Mussy, recently deceased, which is to be placed in the Hôtel Dieu, to which hospital he had been attached for many years.

MR. ELSNER has been appointed Surgeon to Major-General Sir Peter Scratchley, Her Majesty's Special Commissioner for the New Guinea Protectorate, and accompanies him on his tour of inspection amongst the islands of the Pacific.

THE average duration of life in cancer of the tongue is, without operation, ten and a-half months; with operation, sixteen months. In some cases, after operation, the patients have lived for from two to five years, or even ten years.

DR. BARDUZZI (*Giornale Internaz. delle Scienze Mediche*) recommends Guyon's method for the treatment of acute gonorrhœal cystitis. It consists of careful injection into the bladder of 40 drops of a solution of nitrate of silver (5 grains to the ounce) every fifth day, later on 20 drops every second day. This treatment, so successful in acute cases, is absolutely useless in chronic ones.

IN the same journal, Dr. Ceccherelli records the case of a man, æt. 25, who suffered from a large nœvoid lipoma in the left lumbar region. It had existed since he was eleven years old, and completely filled up the interval between the last rib and the crest of the ilium. The tumour altered occasionally in size, becoming also at times the seat of most violent pain. The overlying skin was adherent, discoloured, and ecchymosed. Extirpation was rendered difficult owing to the number of vessels which had to be divided and tied.

WE have heard it claimed for Lyons that there is little fear of cholera breaking out there because the male portion of the population micturate openly in the narrow streets and alleys with which the city is intersected, and that therefrom arises sufficient free ammonia to destroy the cholera poison. The same might be claimed for a good many continental towns besides Lyons, where the act is not confined to the male portion of the population, but cholera finds its way there nevertheless. We hope Lyons will enjoy the boasted immunity during the pre-

sent outbreak, albeit the filthy state of its purlieus may be perpetuated.

LAST week there were 2,885 births in London to 1,472 deaths, the one being almost double the other. This may be taken as some sort of explanation of the enormous increase of the metropolis in recent years, commercial depression notwithstanding.

THE will of Sir William Mure Muir, K.C.B., M.D., Director-General Army Medical Department, Honorary Physician to Her Majesty, has been proved, the personalty being upwards of £8,000.

ON Monday week the Dublin Corporation unanimously voted the freedom of the city to Dr. Kevin Izod O'Doherty. Dr. O'Doherty is the youngest of a family which has occupied a high professional position in Dublin, his eldest brother—lately deceased—being Mr. Doherty, the eminent Dental Surgeon of St. Vincent's Hospital. During his studentship Dr. O'Doherty served as apprentice to Mr. Donovan, of Clare Street, the most esteemed apothecary in Dublin, and at this time he contracted relations with Mr. Gavan Duffy, of the *Nation*, and other leaders of the *United Irishmen* of 1848, the result of which was that he was tried for seditious practices and sentenced to transportation to Australia. After a very long period he returned to Dublin, where he was the first surgeon who received the Fellowship of the Royal College of Surgeons as a first qualification. After a short stay in Dublin he returned to Brisbane, and has practised very successfully in that place up to the present time.

#### EXAMINATION OF CANDIDATES FOR HER MAJESTY'S ARMY, INDIAN, AND NAVAL MEDICAL SERVICES.

##### SURGERY.—MR. POLLOCK.

Monday, 10th August, 1885—from 2 p.m. to 5 p.m.

1. Describe the process by which bone unites in simple fracture. What local and constitutional causes may retard, or prevent union? What should be the treatment under each condition?
2. A child is the subject of disease of the hip-joint. Describe the symptoms by which it may be diagnosed at its commencement; the probable course of the disease if not arrested; and what should be the treatment, local and constitutional, in its various stages?
3. By what symptoms may be diagnosed rupture of the femoral artery, about the middle of the thigh, the result of accident without external wound? What treatment should be adopted in such an injury?
4. What are the various causes of necrosis of bone? What serious consequences may ensue when certain bones are affected; and what should be the treatment according to the bone implicated?
5. What are the various conditions (surgical) which occasion alkaline urine? Describe the measures to be taken to ascertain whether the urine be secreted alkaline, or may have become so after entering the bladder; and the treatment desirable under each condition.
6. Describe the symptoms usually observed in the early stages of syphilitic iritis. Give an account of what would subsequently take place should the disease not be arrested; and lastly describe the treatment in each stage.

##### MEDICINE.—DR. AITKEN.

1. A case for Analysis and Commentary (case of Intra-thoracic Sarcoma).  
Expound the pathology of this case, and state your views regarding the initiation, the progress and development of the symptoms and physical signs, with their mutual relationship

if any; and describe what you would expect to find at the post-mortem examination.

2. A case for Analysis and Commentary (case of Myxœdema).

State the conclusions you come to regarding the pathology and morbid anatomy of this case.

3. Describe the post-mortem evidences in the structures of the heart of acute and chronic endocarditis.

4. Give a short summary of the trophic disturbances which may occur in cases of locomotor ataxy.

5. Classify ovarian tumours on a basis of their origin, development, and morbid anatomy; and state the main points on which you would rely in establishing the physical diagnosis between ovarian dropsy and ascites.

6. Name the drugs and other agents which act on the urinary bladder and urethra, as (1) Vesical sedatives, (2) Vesical tonics, (3) as Urinary sedatives and astringents, explaining how they act, and the indications for their use.

## Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

**SURGEONS' HALL, EDINBURGH.**—At a meeting of the lecturers, held recently, Dr. G. A. Gibson was elected as Lecturer in Materia Medica and Therapeutics. Dr. Gibson is an M.D. and D.Sc. of the University of Edinburgh, a Fellow of the Royal Society, and a Fellow of the Royal College of Physicians of Edinburgh. He is one of the clinical medical tutors in the Royal Infirmary, is Secretary to the College of Physicians, and has during the past year lectured with much acceptance on materia medica in the School of Medicine at Nicholson Square.

**HEALTH OF EDINBURGH.**—The mortality in Edinburgh for the week ending with Saturday, the 15th inst., was 84, and the death-rate 17 per 1,000. Diseases of the chest accounted for at least 20 deaths, and zymotic causes for 9, of which 6 were due to diphtheria, 2 to whooping-cough, and 1 to erysipelas. The intimations for the week comprised—Fever 17, diphtheria 6, scarlatina 8, and measles 16.

**EDINBURGH.—THE LATE DR. WILLIAM WALKER.**—We regret to record the death of Dr. William Walker, of Edinburgh, which took place on the 16th inst., at his residence, 47 Northumberland Street. As a surgeon and an oculist Dr. Walker occupied a position of great eminence, and his loss will be deplored throughout all ranks of the profession, of which he was a distinguished member. A native of Dumfriesshire, Dr. Walker's professional career has always been identified with Edinburgh, where he resided, and where, as an oculist, he was consulted by people from all parts of the kingdom. He held the position of oculist at the Royal Infirmary during a period of thirty-three years; he was a trustee of the Edinburgh Eye Dispensary, in which institution he always took a deep interest; and he had the honour of being oculist in Scotland to the Queen. At one time he was President of the Royal College of Surgeons. He was closely associated not only with the old professional school, in which he rose to eminence, but with the members of the new, the younger school, who looked up to him as a man of outstanding consideration. He was a gentleman who took a most sympathetic interest in the welfare of all classes of the community. Dr. Walker, who was unmarried, was considerably over the great age of three score and ten.

**GLASGOW DEATH-RATE.**—For the week ending with Saturday, the 15th inst., the death-rate of Glasgow was at the rate of 26 per 1,000 per annum of the population, as compared with 25 during the previous week, and 26, 22, and 21 in the corresponding periods of 1884, 1883, and 1882 respectively.

**CHOLERA PRECAUTIONS AT LEITH.**—The lamentable condition of Spain from the terrible epidemic at present raging throughout this fair country and due in "a great measure no doubt to its unsanitary condition, has roused the local authorities in Scotland to the necessity of using every precaution against the importation of the dread disease into this country. At the port of Leith, in order to ensure cleanliness drains and closets are flushed, and white-washing and other sanitary steps have been largely resorted to. The Customs authorities have also boatmen constantly on the look-out at the end of the West Pier to prevent any vessel from a cholera-infected port entering the harbour. This, of course, only refers to a vessel which may have left a port where cholera was known to exist at the time she sailed. In any case, when a vessel leaves a foreign port notice of her destination in this country would certainly be received by the authorities from the British Consul or others abroad before the vessel could well arrive. A double barrier is thus thrown in the way of threatened danger. There are few subjects in which people get "cracked" to a greater extent than on that of "cures," and we are informed that the Spanish Consulate at Glasgow is perfectly flooded with "cures" from hundreds of well-meaning but silly people, and an excerpt from the various "cures" would be found interesting and amusing reading. Do medical men ever lose their heads like the good-natured laymen? Is a nonsensical letter in one of the London dailies purporting to be from Dr. Stretch Dowse, and recommending as much sulphur as will cover a florin, in the shoes, as a cure for cholera, not a practical and cruel joke? If not, how little wonder that intelligent laymen laugh at this and many other vagaries of the orthodox profession.

**SHOOTING ACCIDENT.**—A few days ago, while the Hon. Gathorne Hardy and his son were out shooting, the younger gentleman wounded a rabbit. The animal got among some stones, and the hon. gentleman, wishing to put the animal out of pain, fired among the stones, when some of the shot rebounded, severely injuring the eye of the young lad, who was looking on. Dr. Reid, of Glasgow, was sent for, and the daily papers inform us that "he has successfully extracted the wounded eye."

## Correspondence.

THE LATE HOME SECRETARY AND DR. BRADLEY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR

SIR,—The recent change of Government must be a source of satisfaction to the Medical Profession as a body from one point of view. It is at any rate a relief to get rid of one official whose relations to our profession were, to say the least, extremely unfortunate. The tenure of office of the late Home Secretary was chiefly of interest to us from its association with three prosecutions of medical men. The first was that of Dr. Price, known as the Welsh "Cremation" case; the second that of Messrs. Bower and Keats. Both these were undertaken by the Public Prosecutor at the instigation of the late Home Secretary; both failed, in spite of all the efforts of the Crown lawyers to obtain convictions, and both reflected great discredit on the official responsible for them, that official being the late Home Secretary. Lastly comes the prosecution of Dr. Bradley for a crime neither he nor any other man could have committed, his conviction for a crime with which he was not charged, on the unsupported testimony of a woman known to be the subject of epilepsy, with its accompanying delusions, and in the face of abundant negative evidence of an opposite character. Such a conviction had not a chance of standing; the most superficial inquiry would have been sufficient to show its injustice; and the late Home Secretary showed

himself deaf to the cries of both Justice and Mercy when he refused to look into the question for himself. What was the blasted life of an obscure young doctor to him? He did not show such great-minded equanimity when his own person was thought to be in danger. It is generally understood that on that occasion he showed himself somewhat of a craven. But it is ever so. Those who have the least regard for others have the tenderest for themselves. The late Home Secretary reminds me of the chief actor in a scene I once witnessed. A patient had been drinking heavily and was in a state bordering on delirium tremens, but had a pretty lively sense of his own danger. In an agony of abject fear he cast himself down on his knees before his medical attendant, and with uplifted hands besought him to save his life for that time and he would pay him anything he liked to ask. As might be expected, after such an exhibition of meanness, the individual, when called upon, declined to pay anything at all. In both cases was shown the same lively regard for themselves, and the same absence of regard for others. Sir William Harcourt showed a very lively regard for himself when his own person was threatened, and absolute indifference when it became his duty to step in between a fate worse than the death that threatened himself and an innocent victim. The medical profession has cause to be thankful that he has been removed from his sphere of office, and to hope that he will never again be placed in a position in which he can wantonly insult a body of men belonging to a profession at least as good as his own.

Thanking you, Sir, for your persistent and single-handed efforts on behalf of a brother practitioner,

I have the honour to be, Sir,  
Your obedient servant,

LIVERPOOL.

#### INOCULATION AGAINST CHOLERA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent Dr. Pearse has discoursed so philosophically in the current issue of your journal upon the above question that I, a vulgar-minded reader, am utterly puzzled to make out either premises or deduction from his thesis. The question is, Does he recommend or condemn inoculation for cholera? If he does the latter, as then he and I agree, I need say no more upon the subject. But if he recommends inoculation as a remedy for cholera, I suppose he will carry this new craze so far as to recommend inoculation also for such diseases as enteric or scarlet fever, and for all contagious and infectious diseases, including those with an unnamable and unpleasant name.

As no doubt your correspondent has read the annotation in the *Medical Press* giving the views of Jules Guerin upon the cholera epidemic I will only say that they appear to be orthodox, which I am sorry to say cannot be said of the Spaniard Ferran and his disciples.

Yours, &c.,

Houghton-le-Spring,  
August 22nd, 1885.

J. O'FLANAGAN.

### Special Article.

#### ANTISEPTIC PAVEMENTS.

THE existing system of city scavenging by which the putrescent solids and polluted water are got rid of as quickly as the cleansing organisation permits, and put to rot somewhere else, is obviously very faulty in principle, and its ill effects upon the public health are so manifest that any alternative would be very welcome even at the cost of some additional expense. If it were possible, even in a limited degree, to disinfect street water as it lies in the gutters and as it mixes with decomposing matters we should not only make the decomposition itself much less hurtful, but we should go some way towards making its gaseous and germ emanations less injurious. It is clearly impossible to effect this admixture of antiseptics with street *débris* by any direct means, unless we might, at great expense, effect the object by watering the streets with disinfectants in solution; but a new method has been suggested,

which, if even partially effective, is so economical and convenient that it can be universally applied. It is proposed by the "Hygienic Cement and Sanitary Concrete Company" to lay down pavements, side-walks, sculleries, and in fact all places where dirt is to be found, with a concrete saturated with disinfectants, and it is claimed that so long as any of this concrete remains it will continue to evolve disinfecting gases, and by direct contact with surface water to communicate an admixture of the disinfecting agent to all decomposing material. As to the feasibility of laying down such concrete in all places where such material is suitable, and at no greater expense than other non-disinfecting concrete, there is, we believe, no question; the only controversy which can arise is whether an effective result would be thereby attained. On this point it is unquestionable that the concrete presents all the physical signs of its disinfecting character even after months of wear and exposure to air, water, and attrition. But this apparent efficiency has been submitted to scientific examination by Professor Tichborne, and has stood the test Professor Tichborne had, as far back as 1870, employed himself in the examination of dust got from all sorts of places, and he had ascertained that the dust of cities is, in great measure, comminuted manure, and full of microbes, which fructify readily; and he goes on to say, "if the idea of gradually eliminating an antiseptic through the dust by the attrition of a pavement could be carried out, we should have a permanent hold of these germs." He very reasonably remarks that, if there be one antiseptic less suitable for *permanent* disinfection than another it would be chloride of lime, and yet he found that samples of this concrete contained an appreciable quantity of the disinfectant after twelve months' exposure to air and moisture. He found, moreover, that the concrete so exposed had parted with much of its chlorine to the water in which it was immersed, and that it was found by the tests to contain quite sufficient remaining to deodorise and disinfect sewage. The concrete which was incorporated with carbolic acid yielded, as might be expected, much more satisfactory results. After being six months under water it still yielded a considerable proportion of the disinfectant, and exhaled a strong odour of it. Professor Tichborne comes ultimately to the conclusion from his experiments that the disinfectants "are not easily displaced from the concrete except by attrition," and that this attrition "would be, of course, a more or less constant source of dissemination." Our observation and examination of the cement confirms this opinion, and it seems to us that by its use a very valuable means towards sanitation is presented to us, for it must be recollected that, though the amount of disinfectant evolved were ever so small, the surface of evolution would, if the concrete be generally used, be so large that a very material quantity of the disinfectant would be delivered to the atmosphere without any labour whatever, and, so to speak, in spite of ourselves.

But Corporations are slow-moving bodies, and civic officers are seldom willing to adopt new ideas, and we should not be, therefore, surprised, and would not think any worse of the hygienic cement, if we heard that the Dublin Corporation, or any other Town Council hesitated to use it. They have, however, no right to allow their prejudices or want of knowledge of the subject to interfere with any invention which might be of public benefit, and we hope that they will not fail to put this hygienic concrete to the test, and, if it be found to fulfil its pretensions, to give the citizens the advantage of so valuable a means of health preservation.

Literature

PHARMACOPŒIA OF THE BRITISH HOSPITAL FOR DISEASES OF THE SKIN. (a)

AFTER careful perusal of this collection of remedies, and the mode of applying them, we are pleased with the little work, as there has evidently been a desire to allow simplicity in the formulæ, and a conciseness in the directions.

A PHARMACOPŒIA FOR THE TREATMENT OF DISEASES OF THE LARYNX, PHARYNX, AND NASAL PASSAGES. (b)

THE pages of this work will be found to contain the formulæ of such local applications of remedies as are adapted to the treatment of the various affections of the larynx, pharynx, and nasal passages, and which have been tested by the author in the light of personal clinical experience, and found by him to possess some practical worth. To any one devoting attention to this special subject the perusal of the work will be of great advantage.

THE NEW CHEMISTRY. (c)

"THE New Chemistry" is the title of one of the more recent volumes of "The International Scientific Series." The subject matter of the book first appeared in the form of lectures; these have been remodelled and presented in a handy, illustrated form. The author originally aimed at presenting the modern theories of chemistry to his class, and giving to the philosophy of the science a logical consistency by resting it on the law of Avogadro. But this was soon seen to be inadequate to the purposes and objects of the teacher, and more so, because of the rapid strides in chemistry, and which for many years has been universally active, whereby the world has gained a clearer conception and more comprehensive view of the fundamental principles of the science. But unquestionably the most important advance in chemistry during the last decade has resulted from the study of the thermal changes accompanying the chemical processes, and which prove that the law of the conservation of energy is as important a directing principle in chemistry as it is in physics. This study so far has developed an entirely new branch of the science called thermo-chemistry, and whereby it is expected in the near future we shall be able to predict the order of phenomena in chemistry as fully as we now do in astronomy. The growing importance of the subject led the author, Dr. Cooke, to not only re-write, but add to his original lectures, and he has accomplished his task with so much skill and ability as to bring the whole within the compass of a handy volume, which is in every way suited to the general reader, as the student, both of whom will find that amount of useful information in its pages they may desire to obtain.

Medical News.

Royal Colleges of Physicians and Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.—At the July sittings of the Joint Board of Examiners, held in Glasgow, the following candidates passed the first examination for the triple qualification:—

H. H. Addenbrooke, Wm. Armour, Wm. Bell, Robert Boyle, John H. Brice, Joseph Cantley, Michael Casey, H. Chadwick, Wm. G. Dick, Chas. Doherty, G. H. Douthwaite, M. H. Eames, Chas. A. Fergus, David H. Hamilton, H. L. Homer, Alfred E. Huband, C. B. Humphreys, Samuel Hunter, L. P. Jackson, John E. Jones, John A. Jones, Edward R. Kavanagh, Wm. S. Kidd, James M'Cartney, Michael M'Laughlin, Wm. Magee, Henry B. Maunsell, Patrick O'Gorman, Robt. W. Roberts, John Rogerson, Edmund Ryan, George H. Walker, Wm. Williams, and George T. Woods.

The following passed the second professional examination: Richard Ambler, Dugald Buchanan, Edward Brooks, Edward Clarkson, Edward H. Corder, James Gordon, Edwd. Gray, A. H. Hoffman, John

(a) "Pharmacopœia of the British Hospital for Diseases of the Skin, London," 3rd edition. Edited by Balmanno Squire, M.B. London, Senior Surgeon to the Hospital. London: J. & A. Churchill. 1884.

(b) "A Pharmacopœia for the Treatment of Diseases of the Larynx, etc." By George Moore Wood Lefferts, A.M., M.D., Clinical Professor of Laryngology and Diseases of the Throat, College of Physicians and Surgeons, Medical Department of Columbia College, New York. Second Edition, revised and enlarged. New York and London: G. P. Putnam & Sons. 1884.

(c) "The New Chemistry." By Dr. J. P. Cooke, Irving Professor of Chemistry in Harvard University. London: Kegan Paul & Co. 1884.

Hoyle, John Owen Jones, John Kennedy, Walte H. Large, Walter M'Gibbon, Alexander D. M'Lean, Alfred J. M'Lean, J. A. H. Mogg, Robert D. Prichard, and George Thomas Woods.

The following passed the final examination for the triple qualification:—

Andrew Alexander, Henry Wm. Bryant, Edward Clarkson, Wm. W. Clegg, James Blair Donaldson, M. M. Gandavia, Thos. J. G. Garrett, Walter MacGibbon, Arthur R. Oust, H. N. Rademeyer, David Starrock, and John T. Winter.

The following were admitted L.R.C.P. Ed. and L.F.P.S. Glasgow:— G. C. Bezbaroa and Robert Kerr.

Army Medical Service.—The following is an official list of candidates who were successful for appointments as Surgeons in the Medical Staff of Her Majesty's Army Medical Service at the competitive examination in London on the 10th and following days of August, 1885, in the order of merit:—

Yarr, M. T., ... ..	2980	{ Cox, E. H., ... ..	2350
{ Mills, B. L., ... ..	2830	{ Kennedy, A., ... ..	2370
{ Mumby, L. P., ... ..	2820	{ Gordon-Dill, R. C., ... ..	2345
Melville, C. H., ... ..	2670	{ Skerrett, F. T., ... ..	2140
Wilson, J. B., ... ..	2610	{ Ramsay, H. M., ... ..	2360
Rayner, H., ... ..	2745	{ Stokes, W. B., ... ..	2780
Benny, C. A., ... ..	2707	{ Buchanan, J. B., ... ..	2270
{ Gange, R. E., ... ..	2640	{ Simpson, D., ... ..	2270
{ Kearney, J., ... ..	2630	{ Locker, K. H., ... ..	2215
Thiele, H., ... ..	2679	{ Rose, J., ... ..	2162
Saw, F. A., ... ..	2725	{ Lovie, T. G., ... ..	2100
Cardew, G. S., ... ..	2569	{ Adamson, H. M., ... ..	2161
Cocks, H., ... ..	2510	{ Corkery, T. H., ... ..	2120
Lee, W. J., ... ..	2500	{ Squire, W. P., ... ..	2120
{ Hennessy, F. W., ... ..	2475	{ Crooke, W. E., ... ..	2110
Kendall, H. W. M., ... ..	2440	{ Walsh, C. L., ... ..	2110
Black, J. G., ... ..	2430	{ Brown, H. H., ... ..	2100
Elkington, H. P. G., ... ..	2400	{ Hayman, S. J. W., ... ..	2080
{ Hall, F. W. G., ... ..	2380	{ Hayes, J. P. S., ... ..	2070
{ Tate, G. S., ... ..	2380	{ O'Donnell, J. J., ... ..	2070

Naval Medical Department.—At the competition for commissions in the Medical Service of the Royal Navy, held on the 10th August and following days, in the Hall of the University of London, Burlington Gardens, the under-mentioned gentlemen were the successful candidates:—

Home, W. E., ... ..	2700	{ Moore, J., ... ..	2261
Fitch, R. A., ... ..	2690	{ Mansfield, C. J., ... ..	2100
Beatty, H. B., ... ..	2710	{ Hickson, R., ... ..	2080
Spry, W., ... ..	2700	{ Shuttleworth, H. F., ... ..	2005
Maitland, P. E., ... ..	2380	{ Lowney, J., ... ..	2000
Symonds, G. H. H., ... ..	2360	{ Trevor-Roper, G. D., ... ..	1930
Wynckler, W. J., ... ..	2320	{ Fisher, O. S., ... ..	1960
Walsh, J. J., ... ..	2275	{ Fogarty, J. S., ... ..	1900

Indian Medical Service.—The following is a list of the candidates for Her Majesty's Indian Medical Service who were successful at the competitive examination held at Burlington House on the 11th August:—

Woolbert, H. E., ... ..	3208	{ Cadell, J. M., ... ..	2827
Baker, G. H., ... ..	3005	{ Younan, A. C., ... ..	2725
Grainger, T., ... ..	2915	{ Adie, J. R., ... ..	2622
Edwards, A. R., ... ..	2880	{ Alcock, A. W., ... ..	2760

Twenty-two candidates competed for eight appointments. Twenty-one were reported qualified.

University of London.—The following is a list of the successful candidates at the August intermediate honours examination in Medicine.

ANATOMY.

First Class.—Henry Percy Dean, B.Sc. (Exhibition and Gold Medal); Frederick Howard Taylor (Gold Medal).

Second Class.—Alfredo Antunes Kanthrac, B.A., Percy Ashworth, B.Sc., Alfred Herbert Tubby, Milton Prentice Ledward, Guy Bellingham Smith.

Third Class.—Cyril William Jecks, John Ogle Tunstall, George Ed. Rennie, B.A. Sydney.

MATERIA MEDICA AND PHARMACEUTICAL CHEMISTRY.

First Class.—George Edward Rennie (Exhibition and Gold Medal), \*Ernest Henry Starling, \*Alfredo Antunes Kanthrac, Percy Ashworth, Theodore Fisher.

Second Class.—Evelyn Oliver Ashe, Charles Percival Crouch, Alfred Herbert Tubby.

Third Class.—Milton Prentice Ledward, Walter Stacy Colman, Geo. Hartley O'Reilly, Isabella Macdonald Macdonald, Cyril Cecil Barrow Burt.

ORGANIC CHEMISTRY.

First Class.—Ernest Henry Starling (Exhibition and Gold Medal), \*Henry Percy Dean.

Second Class.—John Wilkie, William Griffith Williams, William Page May, B.Sc.; Arnold Scott.

Third Class.—John Ogle Tunstall, Walter Stacy Colman, John Lloyd Roberts, B.A., B.Sc.

PHYSIOLOGY AND HISTOLOGY.

First Class.—Ernest Henry Starling (Exhibition and Gold Medal), Percy Ashworth (Gold Medal), Alfredo Antunes Kanthrac, Brian Melland, John Lloyd Roberts, John Wilkie.

Second Class.—Cyril William Jecks, Frederick Howard Taylor, Henry Edward Leigh Canney, George Edward Rennie, George Black, Walter Stacy Colman.

Third Class.—William Page May, William Griffith Williams. \* Obtained the number of Marks qualifying for a Medal.

## Notices to Correspondents.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**LOCAL REPORTS AND NEWS.**—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

**DR. W. C. C.** should address his communication to the journal in which the strictures appeared. We have no knowledge of the circumstances.

**MR. G. S.**—We have already contradicted the assertion of a contemporary, which seems not to be conducted on sufficiently honourable principles to acknowledge an error. We cannot again refer to a matter which is entirely between you and it.

### MEDICAL TEMPERANCE IN AUSTRALIA.

WITH temperance principles, hospitals, and institutions so firmly established in our midst, one can hardly understand the opposition of the residents and a section of the profession in Melbourne to the proposal on foot to establish in that city a hospital on temperance principles. Yet the last number of our contemporary the *Australian Medical Journal* asserts that it is so, and that the objectors maintain such firm ground as to compel the upholders of the non-alcoholic treatment of disease to abandon the attempt for the present. Of course, all innovations meet with opposition, and it cannot be expected that the queen city of the New World should be an exception to a general rule. Doubtless the scheme will be carried at no very distant period, and when quietly working as *un fait accompli* it will pass into the natural order of toleration and change.

**MEDICAL OFFICER OF HEALTH.**—The increase is but slight, and not nearly equal to the annual death-rate from the disease at this time of year.

**MR. INCHCOMBE**—The prospects of next year's International Congress are a little less cloudy than announced in a recent number, and we have reason to hope from the latest reports in our American exchanges that wiser counsels will prevail and the causes of the recent split be removed, so that the meeting to which so many in this country and elsewhere were looking forward with interest will now be held in the States as at first arranged. We shall keep our readers *au courant* with the latest phases of the controversy.

**A PARENT (Liverpool).**—It is against our rule to recommend any particular school. We must refer you to the various announcements in our weekly numbers and to our Students' number in September.

**DR. PARSON.**—Having already written upon the subject at some length, we do not think it desirable to re-open it now. Should the discussion that is in progress, however, result in a way that is likely to injure the interests of the institution, it will once more become our duty to expose the dangers incurred.

**MR. SWAN.**—Under the circumstances you cannot be held responsible, however the case results. Your duty ended when the parents' consent was refused; but it is a little doubtful whether you would not have done more wisely had you thenceforth declined all future attendance on the child.

### LIFE INSURANCE.

**ALPHA** asks: In what manner and with what company would you recommend a medical man about to marry to insure his life?

[We would gladly advise our correspondent, but do not like to select a company. We suggest the propriety of his insuring, with profits, in a thoroughly secure company, and settling the policy on his wife, so that it may not be swept away by his debts when he dies.—Ed.]

**ANXIOUS.**—You need have no anxiety about taking your family to Paris. The city is in an unusually healthy state, and there is no prospect of cholera reaching there—at least, at present.

**B. B.**—He would not be justified in quitting his post until leave were granted, except in cases of emergency. Our correspondent does not furnish us with particulars in detail to decide the case in question, but provision should be made for the carrying on of his duties while absent.

**DR. ILLINGWORTH, MR. BRINDLEY JAMES, BRIGADE-SURGEON W. CURRAN.**—Communications to hand shall be considered.

**DR. MACKENZIE (Paris).**—Shall be glad to receive the cases.

### THE BRADLEY FUND.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I have received the following additional subscriptions to those announced in your last issue towards the above fund.

		RICHARD JEFFREYS.	
Chesterfield, Aug. 19th, 1885.			
Mr. Eric Erichsen	.. £5 5 0	Dr. Robertson Match	.. £1 1 0
Dr. Dyson	.. 2 0	Dr. Samuel Mitchell	.. 1 1 0
Dr. Wm. Richardson	.. 2 0	Dr. G. F. Hadley	.. 1 1 0
Mr. C. N. Macnamara	.. 2 0	Dr. Johnston	.. 1 1 0
Dr. Clifford Allbutt	.. 2 0	Mr. Henry Steare	.. 1 0 0
Mr. John Hall	.. 2 0	Mr. John Balnes	.. 1 0 0
Dr. Van Vestrout	.. 1 1 0	Dr. W. E. Higgins	.. 1 0 0
Dr. Martin	.. 1 1 0	Mr. Henry Heywood	.. 1 0 0
Mr. J. F. F. Parr	.. 1 1 0	Mr. W. H. Booth	.. 0 10 6
Dr. R. E. Burgess	.. 1 1 0	Mr. Wm. Dale James	.. 0 10 6
Mr. J. F. Churchill	.. 1 1 0	Dr. Henry Denne	.. 0 10 0
Mr. Matthew Leach	.. 1 1 0	Mr. W. Maxwell Burman	0 10 0
Dr. J. Swain Scriven	.. 1 1 0		

*Errata.* In the last list furnished there were two mistakes. Dr.

Balthazar Foster's subscription should have been £2 2s., and Dr. Francis McLaughlin should have been Dr. Thomas McLaughlin.

**M. B., L.R.C.P.**—The population of Madrid, which is given officially at half a million, does not include the outlying districts, as "greater London" does, and is not included in the statistics of mortality.

**STUDENT.**—The last Wednesday but one in September, as usual.

**DR. WHITTAKER.**—The transmissibility of tuberculosis by vaccination has been shown to be impossible by the results of numerous experiments, those of M. Straus being the most recent to this effect. This observer was quite unable to produce any signs of tubercle in animals he had submitted to vaccination; most careful examination failed to show any characteristic bacilli in the pustules resulting from the operation.

**MR. TOUK.**—We shall not be able to do anything further in the matter until the winter season; even then, however, we cannot promise to take it up again.

**DR. FONTAINE.**—An ordinary saline mixture will probably succeed better than anything else. In order to promote absorption of the effused matter the part should be painted with tincture of iodine.

## Vacancies.

- Brighton.**—Sussex County Hospital.—Honorary Assistant Physician. Applications, with testimonials, to the Secretary, before September 2.
- Chatham.**—St. Bartholomew's Hospital.—Assistant House Surgeon. Salary, £100, with board, &c. Endorsed applications to the House Committee by September 30.
- Coventry and Warwickshire Hospital.**—House Surgeon. Salary, £100 per annum, with board, lodging, &c. Applications to the Secretary on or before September 10.
- Dublin (Cork Street) Fever Hospital.**—Resident (Honorary Assistant) A gratuity of £20 presented on having served six months. (See advt.)
- Leeds.**—General Infirmary.—Resident Obstetric Officer. Salary, £100 per annum, with board and residence. Applications to Mr. Blair, General Manager, before September 10.
- Manchester.**—Owens College.—Professorship of Physiology. Applications to Dr. Greenwood, Principal of the College.
- Shipston-on-Stour Union.**—Medical Officer. Salary, £56 per annum. Applications, with testimonials, to the Clerk, not later than August 28.
- Weston-super-Mare Hospital.**—House Surgeon. Salary, £70 per annum, with board, &c. Applications, with testimonials, to the Hon. Sec., on or before September 5.
- York Dispensary.**—Dispenser. Salary, £100 a year (out-door). Applications, with testimonials, to S. W. North, Esq., Micklegate, York, on or before September 8.

## Appointments.

- BLAKISTON, A., L.R.C.P. Ed., L.R.C.S. Ed.,** Medical Officer for the Wareham and Morden Districts of the Wareham and Purbeck Union.
- CHEETHAM-STRODE, R., M.B. & C.M. Ed.,** House Surgeon to the County Hospital, Huntingdon.
- COLLINS, G. F., M.R.C.S., L.K.Q.C.P.I., L.M.,** Junior Assistant to the Hants County Asylum, Knowle, Farnham.
- COOK, H. S., M.R.C.S., L.S.A. Lond.,** Medical Officer to the Workhouse, Parish of Birmingham.
- GILMORE, R. W., M.B. Dub., L.R.C.S.I.,** Medical Officer for the Broughton District of the Glandford Brig Union.
- HINDLE, J., L.R.C.P. Ed., L.R.C.S. Ed.,** Medical Officer for the Billington District of the Malton Union.
- MATHEW, A., M.R.C.S., L.R.C.P.,** House Surgeon to the Croydon General Hospital.
- MOORE, E. H., L.R.C.P. Ed., L.S. A. Lond.,** Medical Officer for the Mylor District of the Falmouth Union.
- SMITH, G. P., L.R.C.P. Ed., L.R.C.S. Ed., M.R.C.S.,** Medical Officer for the Cheney District of the Banbury Union.
- THYNE, T. M. D. Ed., F.R.C.S. Eng.,** Medical Officer for the Millcorner and Cockfoster's healthy of the Edmonton Union.
- WEBB, T. L., L.R.C.P. Lond., M.R.C.S.,** Medical Officer to the Workhouse, Madeley Union.
- WILDING, W. A., L.K.Q.C.P.I., M.R.C.S.,** Medical Officer for the First District and Workhouse, Church Stretton Union, Salop.

**NAVAL APPOINTMENTS.**—The following appointments have been made:—Fleet-Surgeon T. Henry Knott, to the *Mairebar*; Staff-Surgeon Albert Charles Queely, to the *Conquest*; Staff-Surgeon John B. E. Triggs, to the *Ugent*; Staff-Surgeon William Hayes, to the *Express*; Staff-Surgeon William J. B. Bookey, to the *Royal Adelaide*; Surgeon Jas. W. H. Hawton, to the *Wye*; Surgeon John L. Bagnall Oakley, to the *Minotaur*; Surgeon Clement Alsop, to the *Lion*.

## Births.

**HORNE.**—August 17 at 24 Harcourt Street, Dublin, the wife of Andrew J. Horne, F.K.Q.C.P.I., of a son.

## Deaths.

- ADAMS.**—August 11, at High Street, Lymington, Fants, Robert Seymour Adams, M.R.C.S. Eng., L.S. A. Lond., aged 52.
- NASH.**—August 17, at his residence, Foxedowns Road, Maidstone, London, John Pearson Nash, M.D., Surgeon-Major of H.M. Madras Army (retired), aged 55.
- WALKER.**—August 16, at 47 Northumberland Street, Edinburgh, William Walker, F.R.C.S., Surgeon Oculist to the Queen in Scotland, aged 71.
- WEST.**—August 17, at Royal Marine Terrace, Bray, John Russell West, M.B. aged 35.

## Original Communications.

### ON SOME OF THE DETAILS AND RECENT MODIFICATIONS IN THE ANTISEPTIC TREATMENT OF WOUNDS.

An Address delivered before the Biological Association of the University of Dublin.

By KENDAL FRANKS, M.D., F.R.C.S.I.,  
Surgeon to the Adelaide Hospital, &c.

(Concluded from page 174.)

Now, if we wish to substitute for Lister's method of dressing, a method which, while insuring asepticism, shall not be open to any of these objections we must find a dressing which shall (1) be cheap, (2) which shall be charged with a stable antiseptic, that is, one that will not volatilise at the temperature of the body, (3) which shall absorb powerfully and rapidly, (4) one which will keep the wounds dry, and (5) which shall be easily made, easily kept, and reliable.

A great many different materials have been suggested which, for the most part, are cheap, and which possess a greater or less absorbing power. I will arrange a few of the more important of them in order according to their absorbing power. (a)

Absorbent wool will absorb	15 times its own weight.
Moss-turf " "	8 to 9 " "
Wood-wool " "	8.25 " "
Gauze (freed of fatty substance)	5.5 " "
Jute " "	5 " "
Saw-dust " "	4 to 5 " "

Now we at once observe that first on the list stands absorbent wool, that is, cotton-wool carefully refined and freed from all trace of fat. Such wool, when fully saturated, will hold fifteen times its own weight of fluid. But

(a) These figures are taken from careful experiments made by Neuber of Kiel, and others.

in estimating the value of a material for a surgical dressing, we must take into account not only the quantity of fluid it will hold but also the rapidity, or so to speak, the eagerness, with which it will soak up the fluid. Now, if you suspend a piece of cotton-wool on wire gauze, and allow a fluid such as water to fall drop by drop on its central portion you will find that the central portion will become presently saturated, and will allow the fluid to pass through, whilst the circumferential part of the wool remains quite dry. Hence if you were to apply cotton-wool over a wound, and there were much discharge, the discharge would pass right through the wool opposite to the hole for discharge, whilst the parts of the wool around would have absorbed none of the discharge. Now that is a very important consideration. Suppose you try the same experiment with wood-wool or turf-moss. Each of these should be enclosed in a small bag of gauze so as to make a cushion of it. Now if you allow the fluid to fall *guttatim* on the centre of this cushion suspended in the same way, you will find that the whole pad has become saturated before it will allow any fluid to pass through. In other words, we see that either wood-wool or turf-moss will absorb more eagerly and more thoroughly than cotton wool, though they have not an equal capacity for holding the fluid. Therefore, either of these will fulfil our objects better than cotton-wool. Jute, while absorbing less than any of these, is also open to the same objection. Gauze and saw-dust, though absorbing with rapidity are inferior to turf-moss or wood-wool, both in this respect and also as regards the quantity they will absorb.

From these considerations it will at once appear that any of these dressings are, in these respects, superior to the carbolic gauze, but that the most suitable materials hitherto devised are wood-wool and turf-moss. Between these two there is very little to choose as regards efficiency. Both these materials are extensively used in Germany. Von Bruns, for instance, warmly advocates the use of wood-wool; he has used it largely in hospital practice. It is prepared from finely cut white pine wood, the so-called wood material, which is employed in German

actories for the manufacture of paper. You will see in this sample which I have here that it is of a particularly fine delicate texture; it is very soft and elastic, and is of a clean whitish appearance. It is charged with  $\frac{1}{2}$  per cent. of corrosive sublimate. On the other hand, turf and turf-moss find their strongest supporter in Neuber of Kiel, Esmarch's assistant, to whom we are indebted for the introduction of this material into surgical use. As I have been using both of these materials for antiseptic dressings for some time past, I will tell you shortly the conclusions I have come to. As far as efficiency goes—as far as they fulfil those conditions which we have seen are essential for reaching the ideal after which we seek—I think wood-wool and turf-moss stand pretty nearly on the same level. Wood-wool is undoubtedly a cleaner dressing, but then turf-moss is very much cheaper, at least in this country, and we can easily prepare it for surgical purposes ourselves. Hence I believe that turf dressings will prove the more serviceable.

There are several points in connection with turf dressings which I think are of sufficient importance to merit consideration. Turf as it is found on a moor is composed of two layers or strata. The superficial layer, which, in some places, extends to a depth of 10 or 20 feet, is composed of light brown turf which is often cut up into sods and used for burning. In Germany this superficial layer, usually called turf-moss, is sawn up for burning, and the *débris*, which we call turf mould, or peat litter, is used for a variety of purposes. It is powerfully absorbent, and hence is used largely for bedding in stables. The deeper stratum is composed of what is called black turf. It is very sparingly absorbent, but it is powerfully antiseptic. The turf-moss on the other hand is extremely absorbent, but it is scarcely at all possessed of antiseptic properties. It was these different qualities which suggested to Neuber the idea of making the deep dressing, that lying immediately next the wound, of black turf, and then covering all over with large pads of turf-moss. The absorbing power of the latter is not always the same, under all conditions. If the turf-moss be quite dry it is scarcely at all absorbent. A piece of this brown turf, if quite dry, when thrown on water, will float for a long period of time without absorbing the water to any appreciable extent. But if you place it in water in the moist state, it is then found to be possessed of its full absorbing power, and will rapidly take up eight or nine times its own weight of the water. This is a point to be borne in mind in preparing it for surgical use.

I have said that the turf-moss is very sparingly antiseptic. It is the unnecessary to charge it with an antiseptic previous to use. The most powerful antiseptic which we possess is corrosive sublimate. Compare its potency with that of carbolic acid. An antiseptic, you are aware, may act in one or two ways on organisms. It may either inhibit them, that is it may merely arrest their development, or it may destroy them, so that their power of future growth is for ever gone. Carbolic acid in a solution of 1 in 400, to 1 in 500 prevents the development of germs, but it does not kill them. A weaker solution has no deterrent effect upon them. Corrosive sublimate is much more powerful. A solution of 1 in 300,000 will arrest the development of organisms, while a solution of 1 in 20,000 will kill even the spores of the bacillus anthracis, the most resistant of all known forms of organisms. We possess then in corrosive sublimate a most powerful agent. Moreover, it fulfils one of the desiderata for surgical purposes which carbolic acid does not, it is *non-volatile*. A surgical dressing charged with the sublimate does not lose its strength when exposed to the air. When applied over a wound, the dressing, if sufficiently absorbent, soaks up the discharge, the discharge dissolves the sublimate and thus becomes antiseptic itself, and as the dressings dry by exposure to the air the sublimate does not escape, but remains in the dressing, which will thus be as efficient an antiseptic dressing at the end, say of three weeks, as it was when first applied. A combination then of sublimate as our

antiseptic, and turf mould or wood-wool as our absorbent material, gives us a dressing which allows the wounds to become dry, and at the same time enables us to leave on the dressing for an indefinite length of time, if we so desire, without interfering with the asepis of the wound. We have thus combined in this method, not only a dry dressing, but a permanent dressing. The turf mould, which I have been using for the dressing of operation wounds in the Adelaide Hospital, contains about 1 in 400 of corrosive sublimate. The way we prepare it is this. The turf mould is put into an earthen vessel, and five times its weight of a 1-1,000 solution of corrosive sublimate is added to it. The whole is well mixed up together, and when the turf mould has taken all the fluid up, it is spread out and allowed to dry partially, that is till the whole is reduced to two parts. The turf mould then contains equal quantities of moisture, so that it is in a highly absorbent condition, and it is charged at the same time, as a little calculation will show you, with 1 in 400 of sublimate. It is, therefore, powerfully antiseptic. Now the reason we require it of this strength is, that the turf mould when it is saturated with discharge will be from nine to ten times its original weight, if the turf mould had been dry. But as the turf mould already holds one part of water, it can only absorb 7 to 8 parts more of fluid. The strength of the corrosive sublimate in this saturated dressing will be from 1 in 1,800 to 1 in 2,000. Therefore, the turf mould, prepared in this way, is perfectly reliable even when fully saturated. There is another important point in connection with this method of dressing. We have seen in a typical Lister's dressing, that as soon as the discharge appears at the edge of the dressing, it is necessary to change it. This is not the case with the turf dressing or the wood-wool. As soon as the discharge is seen to have made its way through, it is quite sufficient to apply another pad of the same dressing over it, and to bandage it firmly on. Thus the wound is not disturbed.

But, gentlemen, corrosive sublimate is not an unmixed good. The first cases in which I employed it satisfied me of that. When I applied the gauze bags of turf-mould directly to the skin, both the gauze and the turf having been prepared with a watery solution of corrosive sublimate, and when I came to take the dressings off, say, on the eighth day, I often found the dressings were closely adherent to the skin, and in endeavouring to raise them off, the superficial epidermic layer of the skin peeled off with the dressing, just as if the whole skin had been blistered. This was in fact what had taken place. The corrosive sublimate proved to be extremely irritating, and had given rise to the formation of vesicles, and in a few cases even to pustules. As a general rule the wound was found firmly healed, and, as far as asepticity went the sublimate left nothing to be desired; but in one or two cases the irritation caused by the sublimate had been so great as to delay the healing process. This was a serious drawback, as it was impossible to say beforehand in what cases this irritation would occur. Shortly afterwards Sir Joseph Lister published his address on "Corrosive Sublimate as a Surgical Dressing." (a) I need not enter in detail into that very instructive paper—you ought all to read it for yourselves. I will only now shortly refer to the conclusions at which he then arrived. His experience with corrosive sublimate in watery solutions were much as I have related. It is so irritating that as Sir Joseph Lister states, it made him "at first despair of using corrosive sublimate in anything like a concentrated form as a surgical dressing." He observed however, one interesting fact, that in the immediate vicinity of a wound from which there was much discharge, as in the case of abscess, there was a total absence of all irritation; but towards the periphery of the dressing, evidences of irritation were not wanting. This he concluded was due to the combination of the corrosive sublimate with the

(a) *British Medical Journal*, Oct. 25, 1884.

albumen, and further experiment showed him that this combination was quite unirritating. Now chemists are in the habit of telling us that "albumen forms with corrosive sublimate, an insoluble, or very sparingly soluble, albuminate, and that this albuminate is inert; whence the efficacy of white of egg as an antidote in corrosive sublimate poisoning." "If it were really true," says Sir Joseph, "that the albumen acting in a certain proportion on the corrosive sublimate would form with it an absolutely inactive compound, this would be a very serious consideration for the use of corrosive sublimate in surgical practice. The albuminous (proteid) constituents of the blood are enormously abundant; while the quantity of corrosive sublimate we can use in our dressings cannot be very great. According to the most recent views regarding albumen, its chemical equivalent is about six times that of corrosive sublimate; but the quantity of albuminous material in the serum of the blood is very much more than this in proportion to the sublimate we could think of employing." I cannot now enter into the various and interesting experiments which Sir Joseph Lister has made regarding the action of albumen on corrosive sublimate, but the conclusion he arrived at is too important not to give it to you in his own words: "Thus," he says, "we had evidence that corrosive sublimate forms, with the serum of the blood, a material, whether we call it a chemical compound or not, which retains the properties of the corrosive sublimate, both as to taste and to antiseptic virtue. Now it seems to me highly unlikely that both the characteristic taste of corrosive sublimate, and the antiseptic virtue, would be retained if the corrosive sublimate were decomposed in any way; and, therefore, I venture to think, speaking with all deference to chemists, that we have not here a chemical combination in the ordinary sense, but an association of particles, such as occurs in solution; not an albuminate of mercury, but an albuminate of sublimate, if I may use such an expression; a loose association of particles of chloride of mercury with albumen." We thus see that corrosive sublimate in combination with serum retains its antiseptic properties almost entirely, but it becomes then quite unirritating. Now then let me shortly describe to you how this discovery is applied to our surgical dressings. If serum be mixed in small proportions with corrosive sublimate, in a mortar, a thick, opaque, slimy compound is formed. If, however, you keep on adding fresh serum to it, this material gradually redissolves, and when the proportion of 150 parts of serum to one of sublimate is reached, it yields a clear solution. If we add one part of sublimate to 100 of serum we get a brownish fluid of the consistence of cream; this is the strength which has been found most serviceable, and it is admirably adapted for the preparation of our dressings. If some of this sero-sublimate fluid is allowed to dry, no separation of the crystals of corrosive sublimate takes place, showing how intimately it is combined with the serum. Hence, if gauze be prepared with it, and allowed to dry, the sublimate cannot fall off.

Now, to prepare sero-sublimate in large quantities we require a large supply of serum, and that what Sir Joseph finds the most serviceable and easily attainable is the serum from the blood of a horse. To this serum, one part of corrosive sublimate per cent. is added; we get a thick fluid, such as I have here in this bottle. The gauze then is charged with this fluid, two and a half parts by weight of the fluid being used to saturate one part of gauze. The gauze is then hung up and allowed to dry. It is then ready for use. Now, let me say a few words about the absorbent properties of such gauze. Sir Joseph Lister in his address states that "a gauze will absorb only about three times its weight of liquid." I have, however, found that if you boil the gauze with carbonate of soda to free it from fat, it will absorb five times its own weight. If, therefore, we add to the gauze so prepared,  $2\frac{1}{2}$  parts of the sero-sublimate fluid, we add what will only half saturate it, and, therefore we must knead it well, so as to have the sero-sublimate equally distributed through the

whole. When this sero-sublimate gauze is dried, I find that it will absorb only four times its own weight of fluid, which compared with turf or wood wool, is a very small absorbing power, but is far superior to the carbolic gauze, as it will absorb from three to four times as much.

Now, in order to obtain the greatest amount of absorbing power, combined with the least amount of irritation in a dressing, which, at the same time shall be thoroughly reliable from an antiseptic point of view, I have for some time been adopting the following plan, not merely with satisfactory results, but with results which have often filled me with wonder. After the operation is completed, and all hæmorrhage arrested, and the edges of the wound accurately adapted, I dip a piece of the sero-sublimate gauze in a 1 in 40 solution of carbolic acid. I prefer this to the corrosive sublimate solution on account of the irritation which the latter is likely to cause. Then over this, and covering the skin whereon the dressings shall extend, I place more sero-sublimate gauze. If I anticipate but a small amount of discharge, I place a single pad or cushion of turf-mould, prepared as I have described, but if much discharge is expected, a small one is put on first and a large one over this. The whole is then firmly bandaged on, the elasticity of these pads allowing firm pressure to be applied. The wood-wool is used in the same manner. In most cases these dressings are left undisturbed for eight or ten days, but sometimes they are left on for three weeks. In a few exceptional cases I have taken them off earlier, when, for example I found that the bandages had been applied too tightly. This has occurred chiefly in amputation or excision cases, when I have put on a bandage over the deep dressing and under the turf or wood-wool bags. The question naturally arises, must not the dressings be removed in order to shorten or take out the drainage tubes? I answer, as a rule, no! For I have scarcely ever used drainage tubes, since I have adopted this method of dressing. The manner in which we can dispense with them I shall explain in a few minutes; but it is obvious that if we can dispense with them, a great advantage is gained. We need not then disturb the dressings, and consequently we need not disturb the wound. We are thus able to ensure for the patient the most complete rest. The importance of rest in wound treatment cannot be over estimated. In his work on "Antiseptic Surgery," Mr. Watson Cheyne thus expresses it: "The whole principle of wound treatment may be summed up in the one word, Rest." "The causes of unrest," he further explains, "may be mechanical or chemical." Now, what he means by chemical causes of unrest, is first the irritation caused by the antiseptic, which we have seen is in a great measure obviated by using sero-sublimate; and, secondly, fermentation in a wound. Any method, entitled to be called an aseptic method, provides that fermentation shall not occur in the wound, so that this cause of unrest is practically now abolished. We next come to the mechanical causes of unrest, and chief among these he enumerates the movements of the parts, the presence of foreign bodies, tension due to retained secretions or tight stitches. Now, how far are these causes removed by the typical Listerian method? Let us see what Mr. Watson Cheyne says on this head, and on the carbolic gauze dressing, he is a great authority. In the last chapter of his book, already quoted, he says: "The ideal wound is a subcutaneous one, kept at perfect rest. We have not yet attained this ideal, for even with the aseptic method" (that is the Listerian method) "there is a certain amount of unrest caused by the antiseptic employed, by the stitches, by the apparatus for drainage, and by the dressing itself." This is an excellent summary of the points in which Lister's method fails to reach the ideal. Let us see how much nearer to the ideal the method of dressing, I have just described, brings us. I think you will find that these causes of unrest are almost entirely avoided. Let us examine them in order: *First*, the irritation caused by the antiseptic is, to a great extent, obviated by the use of sero-sublimate in the dress-

ings next the wound. The irritation caused by the antiseptic lotions employed during the course of the operation, we are not concerned with at present, though it is a subject of very great importance. *Secondly*, the irritation caused by the stitches cannot be completely abolished until we can find some means of doing away with them altogether; but the application of sutures in the way I shall immediately describe, to a great extent lessens the chances of any tight stitches being inserted, which might cause disturbance. *Thirdly*, the apparatus for drainage is almost entirely abolished, and with it all possible irritation due to the presence of these foreign bodies in the wound. By substituting for these artificial drains, a natural system of drainage, if I may so style it, we have no foreign bodies left in the wound for this purpose, and therefore it becomes quite unnecessary to take off the dressings in order to remove them. This brings us to the last cause of unrest, the disturbance caused to the patient and to the wound by the dressing itself. I need not now remind you of the dread with which patients usually look forward to the change of dressings, and in young patients especially, the terror which the process not unfrequently excites. Can we suppose that this is not alone a source of great unrest, and therefore one to be avoided as much as possible? But the change of the dressing is equally injurious for the wound. In the first place, it exposes the wound to the risk of becoming infected, although it had escaped during the period of operation, and whilst under the first dressing. We ought not needlessly to run this risk, even though satisfied as to the efficacy of our antiseptic measures. But again, how many cases there are in which absolute immobility of the part is of the utmost importance. Take for example, excision of the knee. You have seen splints devised by the score, the chief object of which is to secure that the limb shall be in a condition of absolute rest. Many of these fail to do so, and yet all of them would probably succeed, if only they were not subject to the disturbance caused by changing the dressings. When our method allows us to apply the dressings and splint at the time of operation, and to leave them absolutely undisturbed for three or even four weeks afterwards, have we not, by this means approached much nearer to our ideal of perfect rest. I am not speaking of possibilities, but of realities. With this method of permanent dressings, I may say I do not frequently take off the first dressing until the wound is firmly healed. Now, with such a method of dressing, what takes place? As the discharge flows from the wound, it meets with a material highly absorbent, and charged with a stable non-volatile antiseptic. This material soaks up the discharge with avidity. The fluid, containing albumen and large quantities, as it passes through the sero-sublimate gauze, dissolves some of the sero-sublimate. That portion of the discharge which enters the turf-mould, forms with the corrosive sublimate which it contains, more sero-sublimate. Should the discharge appear at the outer surface of the dressing, it is itself powerfully antiseptic. Observe, we have no protective next the wound, and no mackintosh or other impermeable material over the dressings, so that the air can pass through and into the dressings. It is rendered harmless by passing through these antiseptic media; but, on the other hand, it plays a most important part in drying the secretions in the dressings. The more the dressings dry, the more powerfully antiseptic they become. Thus, in a few days the dressing has become a *dry dressing*.

Now, when we take off these dressings at the end of ten or fourteen days, what do we find? The dressings are hard and caked, and quite dry. We can raise them all off in one block. The wound beneath is perfectly healed, sometimes only one or two superficial granulating spots are observed, where the discharge had found exit. If the dressings have been left on long enough, say a fortnight or more, we find the outer, unabsorbed portions of the sutures come away sticking to the deepest layer of gauze. I have only occasionally found it necessary to put on a second dressing.

I have already told you, that in order thus to leave the dressings on for a length of time undisturbed, we must get rid of the necessity of taking out or shortening the drainage tubes. This was the problem which Neuber set himself to solve, and his first solution consisted in replacing the rubber tubes, by tubes made of an animal substance, which would gradually become absorbed by the tissues, and which, therefore, need not be removed. The tubes he made out of bone, cut to the proper size and drilled. They were then decalcified, and rendered aseptic. MacEwen endeavoured to improve these by preparing chicken bones, the femur and tibiae most frequently, the articular ends of which were cut off so as to expose the medullary canal. The endosteum and contents of the canal were then cleaned out, the bone decalcified, and holes cut in the side. Now in many cases these decalcified bone tubes acted admirably for drainage, and after they had fulfilled their duty, they disappeared by interstitial absorption. But, unfortunately, this is not always their history. Sometimes when the wound has healed over them, an abscess forms later in the region of the wound, and when it opens, the drainage tube is expelled unabsorbed. This has occurred with sufficient frequency, even in Neuber's own practice, to show that the question had not been correctly solved, and then it was that he gave up the drainage tubes altogether, and endeavoured to procure free exit for the discharges by natural means alone.

Now let me digress for one moment, in order to call your attention to what are called by Neuber, "Buried Sutures." These are sutures employed to bring together the deeper structures in a wound. When, for instance, we remove a tumour from any part of the body, if we bring the skin flaps together at once, we very often leave a cavity underneath, which soon fills with discharge, and which it is very important shall have free egress. The existence of such spaces or cavities in a wound promote secretion from their walls. Sometimes we succeed in preventing these cavities being formed, and so diminish the amount of discharge, by applying pressure in the form of pads on the external skin. But often it is not possible to bring the walls of these cavities together thus. Now this can nearly always be effected by using suture or buried sutures. Before bringing the skin flaps together, in such a manner as to imitate as much as possible the natural condition of the parts, we obliterate the deep cavity by sewing its walls, so that they may lie accurately together. Then, if muscles and fascia have been divided, we sew muscle to muscle, and fascia to fascia, and finally, over all we bring the edges of the wound in the skin together. We thus have no cavities or spaces left in which discharge can accumulate, and as a result we find that the amount of exudation is, as a rule, extremely scanty. The parts thus sutured together unite at once. But we cannot altogether prevent the formation of some discharge, and therefore we must make provision for its easy exit. You will observe in the description I have given, that the parts are adapted by means of a series of sutures arranged in tiers. Now the deepest tier is tied quite tight, the more superficial layer of stitches are still looser, and lastly, the sutures in the skin are the loosest of all. By this means any secretion which may form in the wound naturally makes its way to the surface, where it is eagerly sucked up by the absorbent dressings. If the wound is a superficial one, I do not hesitate to bring the edges of the wound closely together, as in the operation for the radical cure of hernia. In this I never now employ drainage tubes, or make any special arrangements for drainage, and I invariably find them firmly healed on the tenth day, when I usually take off the dressings for the first and last time. Sometimes when we hesitate to absolutely close the wound, the skin suture may be put in obliquely, so as to leave a little pucker at the more dependent end of the wound, through which the discharge may escape, as recommended by Neuber. When we have, however, to deal with a deep wound, it is better to leave gaps between the skin flaps, opposite to the deepest parts of the wound,

through which the discharge can readily escape. In such a case as excision of the knee, Neuber suggested a plan which I have found to give the best results I have seen. The extremities of the incision through the skin, which extends across the front of the knee below the patella are bifurcate, so as to embrace between them a small tongue of skin, the tip of course being above. When the operation is completed, but before the parts are adjusted, these tongues are turned in at each side, and their tips are sutured to the deepest parts of the wound. When the bones are adjusted, these lie behind them, and therefore the discharge, as it forms, flows out over these tongues, and is at once taken up by the dressing. This illustrates the numberless modification which may be adopted, so as, in nearly all cases, to do away with the use of drainage tubes. I cannot now go further into the details of this method. I have said enough to show you how we can, in the first place materially diminish the amount of discharge, and, in the second place, how we can secure free exit for the discharge without the use of artificial drains.

Thus, gentlemen, you see how far we have succeeded in attaining our ideal, the perfect and rapid healing of operation wounds under permanent dressings. Neuber, of Kiel, who has done the greatest amount of work in the promotion of infrequent dressings, states that 80 per cent. of his cases, either heal under a single dressing, or that there only remains some superficial granulating spot which has still to cicatrize. I do not however, desire now to occupy your time with statistics. I have endeavoured to explain to you the lines on which we are working in our endeavours to simplify and improve the antiseptic method. But I have of necessity limited myself to one particular stage, namely, the dressing stage. Time would not permit me to deal with any other stage, but in order to succeed in obtaining the best results from the method of dry dressing, you must supplement what I have already said with two absolutely essential rules. Your antiseptics, both previous to, and during the course of every operation must be faultless, and you must ensure complete hæmostasis. If you will only carry out the most careful antiseptics throughout, the material you dress with is of comparatively minor importance. You can succeed with dressings which have but a small absorbent power, where the antiseptics is perfect; but the best possible dressing will fail, if you neglect the great lessons which Lister has taught. If I have endeavoured to show that Lister's method allows of improvement, I wish you also to remember that to him we owe the great principle of antiseptic surgery, and that were it not for what he has taught, we should still be floundering in the dangers and uncertainties of pre-antiseptic days. Gentlemen, in conclusion, allow me to thank you most sincerely for the patience with which you have listened to an address much longer than I originally intended. I can only plead, by way of apology, the deep interest I feel in the subject, and my anxiety to put before you as clearly as I possibly could the arguments in favour of a method of dressing which I believe will daily gain in favour.

THE

TREATMENT OF PLACENTA PRÆVIA. (a)

By JAMES MURPHY, B.A., M.D.,

Surgeon to the Sunderland Infirmary; Lecturer and Examiner in Botany at the University of Durham College of Medicine, Newcastle-on-Tyne.

(Concluded from page 182.)

THE next treatment which we need consider is the *tampon*. Now, though it is still recommended by several eminent obstetricians, including Luak and Playfair, I would suggest that the day of the *vaginal* plug is gone—it is out of date—it is now as unscientific in principle as it was unsafe in practice; it was unreliable in controlling

hæmorrhage, and was a most fertile source of septicæmia. What is required is a method which will control the bleeding, and at the same time hasten labour, and nothing that I am acquainted with answers these requirements so thoroughly as Barnes's hydrostatic bags, or (as I prefer) Steele's modification of them; and Braun, after many years' experience at Vienna with the colpeurynter maintains the superiority of hydrostatic dilatation, therefore I will not take up your time by discussing the various means which have been adopted for plugging the vagina, but may remind you that should you not have time from the urgency of the case to get Barnes's bags, as once occurred to me, a very efficient cervical plug can be made by the hand, the fingers being joined together in the form of a cone.

The method of Jungbluth, which consists in the *dilatation of the cervix with sponge tents*, I see no advantage in, except that it may be required preparatory to the introduction of a small-size bag; but I have never had occasion to have recourse to it, as in all the cases I have seen the os has been, if not patulous, at least sufficiently dilatable to admit the finger, with a little patience, to be gently introduced, and thus prepare the way for a bag.

The local application of *styptics* I will not stay to discuss—I have no faith in them—but will pass on to the consideration of *version*—(1) external version, both hands being employed on the abdomen; (2) internal version, by means of a hand being introduced into the uterus; and (3) the combined method (the method of Braxton Hicks), when a finger or two are introduced through the os and the other hand is used on the abdomen. Now nearly all the older writers practised version, and this they generally did by forcing the hand through the cervix, seizing a foot, turning the child, and pulling it through the os as rapidly as possible, utterly regardless of the condition of the cervix and os; in fact, the quicker they did it the more they prided themselves on their skill. Well, this was a most disastrous proceeding, and to its continuance may be traced many of the deaths still occurring. The cervix, from its congested and increased vascular condition, is more likely to be torn than in ordinary labour, and a laceration is then more dangerous; not only from the immediate production of hæmorrhage, but from its increased liability to septic absorption. Most writers strongly condemn it, and justly so. External version, as first performed by Wigand, has not been much used; it is in most cases difficult to perform, and having been performed, it would still be useless until the fingers were introduced and a leg brought down. Internal version is often of very great benefit when it is judiciously performed with a fully dilated or easily dilatable os, and has been very extensively employed, and still continues to be so, as the bi-polar method, for some reason or other, has never been taken to kindly in England, the country of its invention. It seems to have been performed by Hamilton in 1822, by Lee in 1843; but was first brought prominently before the profession by Braxton Hicks, in a communication to the *Lancet*, on July 14th and 24th, 1860, in which the treatment of five cases of placenta prævia by this method was described; and the subject was more fully treated in a most able manner in a paper read by him at a meeting of the Obstetrical Society, on the 4th November, 1863. Dr. Barnes (the president, in the chair) spoke in very flattering terms of its advantages, as did also Baker Brown, Hall Davis, Greenhalgh, Graily Hewett, and others.

It has not even up to now taken much hold in America, as King, in the collection of cases occurring in the State of Indiana, found that it was only practised 1 in 240 cases, and the treatment recommended by Luak in his recent text-book differs essentially from the method of Hicks, as he says: "When the cervix has been sufficiently stretched by dilators to admit of delivery, the finger should be introduced, the placenta should be separated, the membranes ruptured, and an extremity seized without passing the entire hand into the uterus. Extraction should follow—the pressure of the fetus prevents any considerable amount of hæmorrhage."

(a) Read before the Northumberland and Durham Medical Society.

DR. MURPHY'S TABLE OF TWENTY-THREE CASES OF PLACENTA PRÆVIA.

Number of Case.	Patient's Age.	Number of Pregnancy.	Name of Medical Attendant.	When first seen.		Month of Pregnancy when Hemorrhage first occurred.	Amount and Duration of Hemorrhage before Treatment.	State of Os when first seen.	Presentation of Placenta.		Treatment.	Result to		Date.
				Month of Pregnancy	Condition.				Placenta.	Fœtus.		Mother.	Child.	
1	27	3rd	Midwife .....	6½	Very faint .....	6½	Very severe for three hours.	Closely contracted	Marginal	Head..	Dilatation of os; separation of placenta; version.	Re-covered	Dead	Dec. 4, 1877.
2	29	4th	Dr. G. Wolford	8½	Extreme collapse; convulsions from loss of blood.	8	Enormous loss after labour commenced; had three floodings previously.	Fully dilated; in labour.	Complete	"	Hand passed by side of placenta; foot immediately seized; version.	"	"	Mar. 12, 1878.
3	35	6th	Dr. Barwick ..	6	Pale, and very faint.	5	Severe flooding for two hours.	Fully dilated; in labour.	"	"	Labour-pains very violent, which rapidly expelled both placenta and fœtus naturally.	"	"	Sept. 14, 1878.
4	32	7th	Midwife .....	Last	Completely blanched, and in an extreme state of collapse.	7½	Great loss on commencement of labour; two previous floodings.	Size of forin; easily dilatible.	"	"	Barnes's bags; separation of placenta; version.	"	"	Mar. 5, 1879.
5	37	11th	Dr. Maling ..	Last	Great faintness ..	7½	Great loss intermittingly for three days while labour was going on; four previous floodings.	Dilated fully; in labour.	"	"	Hand passed by side of placenta; foot seized; version.	"	"	Sept. 28, 1879.
6	42	1st	Dr. Morgan ..	Last	Fairly good .....	8½	Slight hæmorrhage on commencement of labour; two previous floodings.	Size of shilling; very rigid and unyielding; in labour.	"	"	Barnes's bags; dilatation very slow; separation of placenta; Barnes's forceps first, then Barnes's forceps	"	"	Mar. 25, 1881.
7	26	3rd	Dr. Morgan ..	Last	Very good .....	8	Slight hæmorrhage on commencement of labour; two previous floodings.	Size of half-a-crown; dilatible; in labour.	Partial	"	Barnes's bags; dilatation rapid; separation of placenta; pains strong, and labour quickly completed naturally.	"	Alive	Mar. 31, 1881.
8	24	5th	Dr. Murphy ..	Last	Very good .....	Last	A sudden and severe gush of hæmorrhage occurred an hour before I saw her.	Size of shilling, and dilatible.	Complete	"	Barnes's bags; separation of placenta; forceps.	"	Dead	June 21, 1882.
9	33	7th	Dr. Murphy ..	Last	Very good .....	"	Severe on commencement of labour; no previous flooding.	Size of shilling; rather rigid.	Partial.	"	Digital dilatation; separation of placenta; version.	"	Alive	Aug. 1, 1882.
10	37	14th	Dr. Mallis ..	6	Very faint, and blanched.	4½	Hæmorrhage had been going on more or less severely, for previous six weeks.	Would admit tip of finger; rather rigid.	Complete	Breech	Barnes's bags; separation of placenta; all hæmorrhage ceased; foot brought down; fœtus dead and putrid; traction.	"	Dead	Oct. 20, 1882.
11	32	4th	Dr. Bernard ..	8½	Very good .....	8	Once, a fortnight before; no recurrence.	Would admit tip of finger; dilatible.	"	Head	Labour induced by digital dilatation; afterwards Barnes's bags; separation of placenta; version.	"	Alive	Nov. 1, 1882.
12	43	7th	Dr. Bernard ..	7	Blanched .....	6½	More or less continuous for a fortnight.	Would scarcely admit tip of finger; dilatible.	"	"	Same as last case; version.	"	"	Feb. 1883.

\* Phlegmatis alba dotata. † Narrow conjugate diameter; version performed in all labours; only one other child born alive. ‡ Had placenta previa in her last labour. In all the cases, as soon as the placenta was separated sufficiently, the hæmorrhage ceased completely, or became so very trivial as to be of no consequence.

In France, it does not seem to have taken hold even at the present day, thus Wasseiga (1881) only mentions it in remarking that "its application is limited to rare cases, for should it not succeed, we would render ordinary version more difficult—the membranes being ruptured by the attempt," and Charpentier, in his new and extensive text-book, published in 1882, does not even mention it in connection with the treatment of placenta prævia.

It was at first rejected in Germany, more especially by Hecker, Spiegelberg, and Müller; but it slowly made its way, and is now warmly advocated by several, including Hoffmeier, who was the first to give it an extensive trial in hospital practice, then by Behm, Schmidt, Lomer, Kuhn, Fasbender, Martin, and Kaltenbach. And as Lomer has recently gone so fully into the question in the paper before alluded to, I cannot do better than describe in his own words the method as practised in Schröder's Clinic in the University Hospital for Women in Berlin. "Turn by the bi-manual method as soon as possible, pull down the leg and tampon with it, and with the breech of the child the ruptured vessels of the placenta. Do not extract the child then; let it come by itself, or at least only assist its natural expulsion by gentle and rare tractions. Do away with plug as much as possible; it is a dangerous thing, for it favours infection, and valuable time is lost with its application. Do not wait in order to perform turning until the cervix and os are sufficiently dilated to allow the hand to pass. Turn as soon as you can pass one or two fingers through the cervix. It is unnecessary to force your fingers through the cervix for this. Introduce the whole hand into the vagina, pass one or two fingers through the cervix, rupture the membranes, and turn by Braxton Hick's bi-manual method. Use chloroform freely in performing these manipulations. If the placenta is in your way try to rupture the membranes at its margin; but if this is not feasible, do not lose time—perforate the placenta with your finger, get hold of a leg as soon as possible and pull it down. This may cause a very strong hæmorrhage at the moment. Hoffmeier and Behm have already remarked this, and I can fully confirm their observation. This is the only critical moment in the operation. The operator must be prepared for it, and must not lose his presence of mind when his hand is suddenly covered with a stream of blood. He must remember that the most alarming hæmorrhage will cease with positive certainty when he pulls down the leg of the child. Up to this moment the treatment is an energetic, active one. Experience shows that flooding now ceases. The next part of the treatment is of an expectant nature. A quick extraction made now would cause rupture of the cervix, and fatal post-partum hæmorrhage. Wait, therefore; give the patient time to rally her powers; wait until pain sets in, and then assist nature by exerting slow and gentle tractions if the child is in danger during this time. Let it run its risk, let it die if necessary, but do not endanger the mother by quick extraction. Cervical laceration is always a dangerous thing—it is particularly dangerous in placenta prævia, on account of the great vascularity of the tissue of the cervix and its liability to rupture. Atony of the uterus is also a disagreeable complication, especially in cases of placenta prævia, when there generally is not too much blood to lose; but these dangers may be got rid of by an expectant treatment. After turning, pains generally set in quickly, the cervix distends rapidly, and the child is born generally between one and two-and-a-half hours after turning."

He then discusses the method under five heads:—

1. How should we treat cases of flooding occurring during pregnancy? and states that his cases have not proved to him the necessity of bringing on premature labour, but goes on to say, "when strong hæmorrhage occurred in pregnancy, we use the tampon and examine a few hours later, to see whether the cervix was sufficiently dilated to allow one finger to be passed, and to permit of turning to be performed." In this sense, he confesses, his method may be counted perhaps among the

proceedings having the object to induce premature labour in placenta prævia, and further says, "operators who have lately followed this plan have had very good results," paying me the compliment of quoting me as an exponent of it, saying that my cases "show that the adoption of active measures early is the right thing for placenta prævia."

2. Is bi-manual turning an easy operation? To which he answers in the affirmative—in which all who have practised the method frequently will concur—and recommends chloroform to be freely given in all cases.

3. Can we rely on hæmorrhage ceasing after turning? Replying, that notwithstanding all views to the contrary, it is a matter of fact that hæmorrhage does cease.

4. How long must we wait for the child to be born by natural powers? That delivery takes place in from one to two-and-a-half hours. Behm generally allows the children to be born quite spontaneously, and had to wait from half-an-hour to four hours, and in one case for eleven hours.

5. Ought the method of rupturing the membranes in head presentation be abandoned altogether? He says circumstances must decide. When the placenta is only felt marginally, when the head has entered the pelvis, when pains are strong and hæmorrhage not very profuse, then rupture of the membrane seems to be the right thing. It must not, however, he says, be forgotten, that in adopting this method of treatment the chances for effecting an easy version are lost; and as sometimes hæmorrhage does not cease after rupture of the membranes, turning has then to be resorted to under favourable circumstances, and approvingly quotes King, who says "that the evacuation of the liquor amnii, if performed before the os is dilated, is an unreliable agent, and ought not to be classed as a means for controlling the hæmorrhage."

I have thus quoted very fully from Lomer, as he represents one of the greatest midwifery schools in the world; and the treatment he recommends has had such extraordinary success in Germany that I am anxious that it should be placed before the Society in the words of one who has had a large experience of it, more especially as I have never had recourse to it, the results of the methods which I practise having hitherto been so good that I am loth to leave them, and I am strongly inclined to believe they more fully prevent hæmorrhage and give the child a better chance.

The practice which I follow consists, not in a single method for stopping hæmorrhage, but in several, and it is this: In the first place, in every one of my own patients, or in those that I am consulted about, when hæmorrhage occurs after the seventh month, when it is clearly not from the cervix or os, and when there is presumptive evidence that it is from placenta prævia, I advise premature labour to be introduced, or before that period of pregnancy when the hæmorrhage is severe, continuous, or frequently recurring. In cases that permit of a little delay from the symptoms not being very urgent, I appoint a time when I can give a few hours' continuous attendance—two hours is generally sufficient; as once you commence to induce labour, I consider it necessary to remain with the patient until delivery is accomplished; and when the case does not command instant action one can fix his own time and can have what assistance he requires.

I find having an assistant a great advantage, and by thus arranging a definite time practitioners can secure the services of a specialist or fellow-practitioner to help them and share the responsibility. On examination, if the cervix will permit it, I introduce my finger, separate the placenta all round, and then put in a Barnes's bag; and if not I gently and slowly insinuate my finger through the os, which I have always found easy of accomplishment, never having had recourse to the preliminary introduction of a tent, though in inducing premature labour for other causes I have frequently had to introduce tupulo tents. Having thus dilated the cervix

with my finger, I separate the placenta freely around the internal os, and at once introduce a Barnes's bag. I slowly fill it with water—and here let me give a practical hint on the use of hydrostatic bags, which I do not remember to have seen mentioned in any of the text books: When the bag is well through the cervix it is very difficult to say how full it is, and by continuing the injection it may very easily be burst, as once happened to myself, and has, I know, happened to many others; so to avoid this it is desirable to ascertain and remember how many syringefuls each bag requires before being fully dilated, and then to carefully inject only that number. Having thus filled the bag, I wait patiently until the os is well dilated around it, and, before introducing another one, separate the placenta further should the hæmorrhage continue, which it does not provided the placenta has been sufficiently separated at first. After the bag has been introduced for some time the pains come on fairly well, though as a rule they are not very strong.

I thus proceed until the os is fully dilated, when I give ergot freely and decide what is the most suitable course to follow. If the placenta is lateral or marginal, and the pains fairly strong, I rupture the membrane and leave the case to nature; or if the head is well into the pelvis, I may apply the forceps; but in the great majority of cases I perform version, preferably by the combined method, and deliver the child as quickly as is consistent with safety to the mother. Bearing in mind that the os is now fully dilated, this practice is essentially different from the old *accouchement forcé*.

If I may offer a suggestion as to the course to be followed in the discussion, it will be this—

1st. How are cases of flooding from placenta prævia to be treated during pregnancy?

2nd. Is labour to be induced—if so, when and how; if not—what treatment should be followed?

3rd. What is the best method of conducting the labour so as to stop the hæmorrhage and give the best chance to the mother and child?

This latter question is one which is pre-eminently deserving of the attention of the Society, as in all the methods I have discussed the mortality to the children is very great.

In conclusion, Sir, I beg to thank you and the members for the patience and attention in which they have followed my rather lengthened remarks, and I have much pleasure in presenting to the Society a complete list, drawn up in tabular form, giving particulars of all the cases of placenta prævia I have seen, 23 cases without a single maternal death.

## HISTORY OF THE PROGRESS OF LARYNGOLOGY FROM THE EARLIEST TIMES TO THE PRESENT.

By GORDON HOLMES, M.D.,

Physician to the Municipal Throat and Ear Infirmary, London; Consulting Physician to the Sheffield Ear and Throat Hospital.

Il importe beaucoup de connaître l'histoire de la science à laquelle on s'attache.—Boerhaave.

### EPOCH I.—THE PRE-LARYNGOSCOPIC AGE.

(Continued from page 187.)

PREVIOUS to 1790, P. J. Desault, surgeon to the Hotel-Dieu, re-introduced the ancient practice of passing a tube into the larynx for the purpose of providing a sufficient breathway in cases of "laryngeal phthisis" attended with dyspnoea. He supposed that this procedure would often avert the necessity for tracheotomy. His method was to push a flexible tube through the nose and hence down the pharynx into the larynx. A partial success attended the operation, which was tried in many cases and executed with great dexterity, it is said, by Desault, but it never gained a very general acceptance. Petit, (25) however, who gives the first pub-

lished account of some of Desault's devices, thought highly of this "laryngeal sound," as it was called.

To Desault also is due the first suggestion of thyrotomy, then called laryngotomy, but the operation does not seem to have been performed in his own time. He merely proposed it as a last resource when disease of the laryngeal cartilages was present, and he thought a chance of the ulceration healing might be afforded by removing the carious parts after laying open the larynx. The first instance in which the thyroid cartilage was actually divided occurred in 1788 (Pelletan's case). (26) It was performed for the third time in 1833 by Brauers (27) of Louvain, in a man, *set.* 40, for a laryngeal tumour. It turned out to be a case of malignant disease, and the growths resprouted several times after removal and cauterisation. The patient lingered for some weeks or months, his death, though not recorded, being foreseen as proximate. In 1844 for the third time it was undertaken by Ehrmann (28) with complete success, in a female, *set.* 33, for the extraction of a polyp. Two days before he had opened the trachea and introduced a canula.

The greatest credit, however, is due to Horace Green (29) in connection with the treatment of laryngeal growths for being the first who attempted (and with success in two cases) their removal *per vias naturales*. The first case was that of a little girl, *set.* 8, who for long had shown signs of laryngeal obstruction. On strongly depressing the tongue a pedunculated polyp, nearly as large as a cherry, was, after some time, discovered during forcible expiration. It was seized with a double hook and severed by a slender probe-pointed knife passed down towards the glottis. In the second instance, that of a man, *set.* 42, cauterisation with silver nitrate and manipulation of a probang in the larynx brought away piecemeal on several occasions a "cauliflower excrescence," and the patient lived for many years greatly alleviated.

Respecting the rarely practised operations crico-thyroid and thyro-hyoid laryngotomy, it need only be stated that the former was devised by Vicq d'Azyi (30) in 1776, and the latter by Malgaigne (31) about 1850. In 1859 the supra-hyoid operation was performed for the first time by Prat, (32) a French surgeon, and a growth was successfully removed.

Scarification of the larynx for the relief of oedema was first proposed by J. Lisfranc (33), Professor of Medicine at Paris, in 1823. He advised the use both of the finger-nail and of a curved knife, and reported briefly six cases so treated, in five of which recovery ensued without tracheotomy. After his time the operation was frequently tried, and several modifications of the laryngeal lancet were made according to the mechanical preferences of the various operators.

#### EPOCH II.—THE LARYNGOSCOPIC AGE.

THE epoch-making invention of Garcia and Czermak resulted naturally from the recognition of the great physiological and pathological importance of the larynx. The laryngoscope did not create laryngology; on the contrary, that science having attained a wide extension evolved an instrument essential to its practical aims. Without the laryngoscope laryngology was scarcely thought of outside the laboratory; it was a science without the application to the wants of everyday life, a system of pathology cut off from clinical practice. But Czermak, in completing the invention, threw a bridge across the chasm, and laryngology at once lost its recondite character; medicine was enriched by a field of disease newly thrown open for daily observation and treatment; workers in it, continually increasing in numbers, started up in every quarter of the world, and the average practitioner of to-day has a personal knowledge of diseases of the larynx rarely possessed by the medical professor of pre-laryngoscopic years.

As early as 1825 Cagniard de la Tour, eager to solve the difficult problem of voice production, tried to see the larynx by passing a small mirror into the pharynx. In 1832, Babington, impelled by the exigencies of diagnosis, made a similar attempt, and matured a laryngoscope, complete even to the artificial illumination. Independently or following their example the conception of laryngoscopy was put into practice by many others, (34) but not until 1854 with decided results. In that year Manuel Garcia, a teacher of singing, intensely desirous of elucidating the physiology of the voice, made persevering efforts to observe his own larynx. Holding a dentist's mirror in his pharynx, he placed himself before a looking-glass, allowing the full sunlight to enter his throat. Iguerant of previous trials, he

was not guided by the history of former failures, but he succeeded in his object, and published the first description of the action of the larynx in life. So far physiology was illustrated, but pathology remained an unlighted field, Czermak (35) was the sun that rose upon it. He first made himself familiar with the laryngeal mirror by practising on himself, and then facilitated its use on others by re-introducing and simplifying the employment of artificial light. In 1858 he gave demonstrations of laryngoscopy in the principal cities of Europe, and henceforward medicine entered into the practical possession of the laryngoscope.

It may be instructive to inquire why Garcia succeeded when before him so many had failed. The explanation is, doubtless, that practice was necessary in order to be able to use the laryngoscope fruitfully, but either this fact was unrecognised, or the difficulty of fulfilling the condition in observing other persons baffled success. The idea of laryngoscopy was simple, to carry it out seemed equally so, but the first trial disappointing expectation, final insufficiency was concluded. The sick patient was the worst possible subject for experiments, but immediate results were demanded. Garcia, however, in betaking himself to autoscopic observation discovered perhaps the only path leading to the desired end. Here the sensitiveness, awkwardness, or want of interest of another person did not stand in the way of perseverance, and the slightest point being gained the investigator was encouraged, and could proceed without obstacle. The truth of this solution is well illustrated by the progress of the invention after Garcia. Thus, in 1857 Türk, of Vienna, tried to take advantage of the device in examining hospital patients, but after a few months laid aside the instrument as impracticable for the purpose. On the other hand, Czermak, having fortified himself by autoscopic training, soon apprehended the requirements of clinical laryngoscopy, and accordingly perfected the application of artificial light.

The intrinsic advantages derived from the laryngoscope will appear fully when treating our subject in its special divisions, but those who have studied the progress of laryngology in former periods will be prepared to find that few actual discoveries have attended the use of the instrument, and that hence the close of this record will not be long deferred. The almost numberless papers, valuable for minute discussion and speculation as to undecided questions, or for the dissemination of laryngological knowledge, do not, of course, come within the scope of this history, which deals almost exclusively with such salient advances as can be described intelligibly in a few words.

(25) *Op. cit.* The "Ouvrages Chirurgicales, ou exposé de la Doctrine et de la Pratique de P. J. Desault" were posthumous (after 1796, the date of his death), and were written, not merely edited, by Bichat.

(26) See Flanchon, *Faits cliniques de laryngotomie*, Paris (Thèse), 1860. Brauer's and Ehrmann's cases are generally given the credit of being the first.

(34) The history of attempts at laryngoscopy before Garcia having been given very fully by Windsor, Guillaume, Mackenzie, Fauvel, and others, need not be recapitulated here.

(35) Johann Nepomuk Czermak, of Prague, (1822-1878) attained great popularity as a professor of physiology, which subject he taught successively at several German universities, ultimately at Leipzig.

(To be concluded in our next.)

## Clinical Records.

### ST. VINCENT'S HOSPITAL, DUBLIN.

#### *A Case of Removal of Tongue.*

Under the care of B. F. TOBIN, F.R.C.S.I.,

Assistant-Surgeon to St. Vincent's Hospital; late Assistant-Professor of Surgery, Army Medical School.

As unsuccessful surgery is oftentimes more instructive than that which leads to a happy result, it may not be idle to publish the following case:—

The patient, a man, *set.* 65, was admitted into St. Vincent's Hospital on August 5th, suffering from epithelioma of tongue. The disease, stated to be two months in existence,

had had its starting point from the left border of the tongue, and on the day of admission had infiltrated the left side of that organ to near its centre from a point half an inch from the tip to one one inch from the base, and the underlying floor of the mouth to about the same extent. No induration of the glands in the neck could be detected. The patient requested that some operation should be undertaken for his cure, and persisted in his request after the dangers of the operation and the probabilities of the recurrence of the disease had been explained to him. Accordingly on August 11th, the following operation, introduced by Professor Kocher, and described by Mr. Barker, was performed:—

The patient being under the influence of ether, tracheotomy was performed, after which the pharynx was carefully plugged with a sponge, an incision was then carried along the internal border of the left sterno-mastoid from the tip of the ear to the cornu of the hyoid bone, then forward to the body of that bone, and finally upwards along the anterior belly of the diaphragm to the symphysis of the jaw. After fully reflecting the flap so mapped out, the lingual and facial arteries were ligatured close to their origins, and an indurated gland that lay embedded close to the carotid was dissected out. The left sub-maxillary gland was next removed, and then the tongue having been well drawn out of the mouth by means of a previously inserted ligature, it, together with the left sub-lingual gland and the entire mucous floor of the mouth on the left side were removed, the attachments being divided with a scissors from behind forwards. On division of the right lingual artery no hemorrhage occurred, but on drawing forward the tissues in its neighbourhood for inspection it was seen to spout and was secured by a ligature. The sponge in the pharynx was now changed for another, behind which a tube was made to pass into the œsophagus, and into the large gap in the floor of the mouth a sponge well sprinkled with iodoform was pressed. The wound was closed with sutures except at the angle of jaw where a drainage-tube was inserted. The patient bore the operation well, and was put back in bed breathing quietly through the tracheotomy tube. At 6 p.m. and 11 p.m. his condition was most favourable; temperature 99.8; respirations 16; pulse 74; and at each of these hours he was given a nutrient enema, and a few ounces of strong beef tea through the œsophageal tube.

At 2 a.m. it appears that he began to be troubled with cough, and the tracheotomy tube had to be cleared more than once. At 4 a.m. he was seized with violent symptoms of choking, and Dr. R. McArdle, the house-surgeon, who was present at the time, found that the tracheotomy tube had been coughed out. He replaced the tube, used artificial respiration, and sent for me. When I arrived the patient had rallied a little, but his condition might still be described as moribund. As, after waiting a short time, no improvement seemed to take place, I decided to withdraw the sponges that plugged the pharynx. I withdrew one, and an ounce or two of what appeared like fluid from the stomach flowed with it. I then removed the other, that which had been inserted in the wound, and which partially blocked the larynx, and immediately the patient ceased to breathe. After this, further attempts at resuscitation gave no result.

On thinking over the case I am led to believe that what happened immediately before death was this: Vomited fluid partially displaced and saturated the sponges in the pharynx and mouth. Some of it trickled into the trachea and induced the efforts that expelled the tracheotomy tube, and there was a further influx of fluid when I withdrew the sponges.

Lest the painful termination of this case should prejudice the form of operation employed, I wish to make the following remarks. The incision recommended by Prof. Kocher seemed to me, during the performance of the operation, to leave nothing to be desired in the facility it gave for removing the entire tongue, and the glands in its neighbourhood. The view obtained of the parts it was necessary to divide was very good, and the one incision gave free access to the glands at side of neck, the lingual artery, and the attachments of the tongue. The operation, though tedious, is not one difficult of performance, especially if the operator has near him anatomists as able as those who guided me. Of the advisability of putting a plug in the pharynx after the operation, so as to close the larynx and compel the patient to breathe solely by the opening in the trachea, I am

in doubt. It certainly guards against the danger of septic lung inflammation, but on the other hand it seems to block in a dangerous locality anything the patient may happen to vomit. Would keeping the patient in a prone position help us in these after-operation difficulties? That such is the proper position during the removal of dressings the present case illustrates, and I see nothing against such a position being continuously assumed as long as the secretions of the wound remain septic. How far a table that could be raised to a convenient height, and reflected, or electric light, would help one to dispense with tracheotomy in such operations as the present is also a question of great interest.

#### EXAMINATION OF CANDIDATES FOR HER MAJESTY'S ARMY, INDIAN, AND NAVAL MEDICAL SERVICES.

(Continued from page 197.)

##### ANATOMY AND PHYSIOLOGY.—SIR JOSEPH FAYRE.

1. Describe the wrist joint; giving an account of the various structures which enter into its formation, and the parts of importance which are in immediate relation with it.
2. Describe the origin, course, anatomical relations and distribution of the axillary artery, and of its branches.
3. Describe minutely the structures which enter into the formation of a liver lobule, and how they are related anatomically to each other. Enumerate the functions of the liver, and dwell in detail on that which relates to the secretion of bile.
4. Describe the minute structure, the innervation, blood supply, and anatomical relations to other parts, of the iris. Give an account of its functions in respect to vision, its mode of action and the means by which its movements are effected.
5. Describe the dissection (through the perineum) by which you would expose the prostate gland and prostatic portion of the urethra, giving an account of the parts in the order in which they are exposed or divided.

##### CHEMISTRY.—DR. ALLMAN.

1. What is the composition of the atmosphere? In what manner are its constituents combined?
2. Organic food-substances may be divided into two classes—the nitrogenous and the non-nitrogenous. Give some examples of each of these classes.
3. In what does the difference between hard and soft water essentially consist? By what means may certain forms of hard water be softened?
4. Give the chemical formula for the composition of Calomel, and also that for the composition of Corrosive Sublimate. How do these two substances differ from one another in regard to their solubility in water?

##### NATURAL SCIENCES.—DR. ALLMAN.

[N.B.—“Not more than one question in each subject.”]

##### ZOOLOGY.

1. Give one or more examples of the class *Amphibia*. On what grounds have the Amphibia been separated as a distinct class from the *Reptilia* with which they had been previously associated?
2. Describe the respiratory system of the *Insecta*.
3. What are the essential characters of the *vertebrata*? Enumerate the classes of this sub-kingdom.

##### BOTANY.

4. What are *stomata*? Where are they chiefly found?
5. What is meant by *Protoplasm*? What examples would you select for demonstrating its presence and activity in the vegetable kingdom?
6. What is a *bisexual*, and what a *unisexual* flower? Adduce an example of each from the plants contained in the Pharmacopœia.

##### PHYSICS.

7. State the evidence from which we conclude that a charge of electricity imparted to a conducting body resides only on the surface of the body.
8. What is meant by the statement that water has a *maximum density*? What purpose is served by this property of water in the economy of nature?
9. What is a *glacier*? From what evidence are we justified in asserting the former existence of glaciers in regions where they no longer occur?

## Special Article.

## CHOLERA.

WE learn that Dr. Ermengen, of Brussels, has, in company with Dr. Paul Gibier, studied the subject of anti-choleraic inoculation as employed by Dr. Ferran in Spain. He reports as follows: On our arrival in Madrid M. Ferran received us most kindly, and placed at our disposal all the necessary instruments for investigation. We first obtained by means of cultivation, specimens of pure comma-bacilla, and with these inoculated several persons. Although these cultures were twenty-four hours old when I examined them there was very little micro-organism to be seen. I did not notice either *oozones* or *oospheres*, such as M. Ferran said existed in the cycle of evolution of the cholera microbe, the only life to be seen was the thin comma-bacilla of Koch, and it was not mixed with the spiral forms of organism. In an older cultivation we discovered round corpuscles which resembled crystallised salts artificially prepared. They were much larger than the other microbes. These M. Ferran called *muriform* bodies, and they were thought to be the spores developed by the comma-bacilli, and consequently the veritable cholera germ. But after several experiments it has been finally decided that these are *inorganic* germs, and complete strangers to the cycle of evolution of the cholera microbe. They disappear entirely in chlorohydric or acetic acid. M. Ermengen studied carefully the spherical masses or globules found in the filamentary forms of comma-bacilli, and called *oozones* and *oospheres* by Dr. Ferran. The conclusions he arrived at are that these are not *monstrosities* or *forms of involution*, but that their form and other characteristics make them essentially different from the globular masses found at the ends of wave-like filaments. They are frequently found in other cultivated liquids, and he thinks with M. Hueppe that they are organs of reproduction like arthrospores. M. Ferran inoculated his subjects twice over with vaccine of different attenuations. Four or five hours after the first inoculation of one centimetre of liquid under the skin on the upper part of the two arms, tumefaction set in, accompanied by heat, a reddish appearance, and some pain. The inflammation gradually increased, until in twenty-four hours it extended to the elbow, and it lasted two or three days. It was generally accompanied by slight fever, shuddering, &c., and in one or two cases a little diarrhoea was brought on, but that might have been simply a coincidence. There were no cramps or cold in the extremities, and altogether the inconvenience felt was very slight. Of course, to obtain these results, great care must be taken to use properly attenuated liquid. M. Ferran stated that he found in the blood of those inoculated numbers of comma-bacilli; but after careful investigation neither M. Gibier or his colleague could discover these organisms. After the second vaccination the symptoms were similar, but less intensified; in fact, the first inoculation produced a sort of immunity to the infection.

It was stated in the *British Medical Journal* that those vaccinated for cholera suffered from gangrenous abscesses, blood poisoning, &c., M. Ermengen visited the hospitals to investigate this statement, and only found 6 or 7 cases of slight abscesses out of 300 persons vaccinated, and none of blood poisoning.

The following figures will show some of the results of vaccination in the village of Alcira in Spain, which is low-lying and badly supplied with water, and which is kept in a most insanitary condition. Of 16,000 inhabitants, 9,100 were vaccinated once, and 7,500 twice. Of these there were—

	Not vaccinated.	Vaccinated once.	Re-vaccinated.	Total.
Attacked ...	261	32	27	320
Died... ..	120	7	3	130
Recovered ...	99	20	19	138
In treatment	42	5	5	52

From this and the remaining evidence the only conclusion that can be arrived at is that in Alcira, where the half of the population were vaccinated, three times as many died of those who were not vaccinated as of those who were. Owing to a disagreement between the professors and M. Ferran the investigation could not be concluded in Spain, but will be continued separately by each of these gentlemen.

The conclusions arrived at are—

1. That Koch's comma-bacilla exists in the intestines.
2. That the liquid used for vaccination by Dr. Ferran was obtained by cultivation of the cholera microbe.
3. The liquid taken for the second vaccination contained the microbes, very small and not further developed than at first.
4. The corpuscles which Dr. Ferran called *spores* are probably inorganic. In any case, it has not been proved that they have any biological function.
5. The *muriform* bodies described by Dr. Ferran as developed by the spores are crystalline masses, as is proved by their solubility in acids, their characteristic forms, and their dimensions.
6. The subcutaneous injections of the vaccinal liquids produce local irritation and slight fever, unaccompanied by any choleraic symptoms.
7. The results of *re-vaccination* are similar to those of the first inoculation.
8. The blood taken from six vaccinated persons was found to be in a normal condition.
9. It remains to be proved that the local irritation produced is caused by vaccine, and not by the bile used by Dr. Ferran in his cultivation.
10. None of the cases observed by Dr. Ermengen produced harmful results.

All the remaining evidence is incomplete, and must be proved by future investigation.

As a corollary to our notice last week of the conferring of the Albert medal upon Dr. Thompson, of the Tyrone Infirmary, for his self-sacrifice in sucking the diphtheritic material from the throat of a dying child, we notice that the medical officer of the hospital at Nikolaief has just died of diphtheria, which he contracted from a child when painting its throat. The patient coughed some of the diphtheritic material in his face. He was only ill for three days.

THE funds of the City of Dublin Hospital, which had been reduced owing to the failure of the Munster Bank, have been considerably served by a theatrical performance during the whole of last week. Over twenty military officers and other persons of rank took part. This week the performance is to be repeated for the benefit of the Meath Hospital.

At the Dublin Zoological Gardens two animals of great interest have just been acquired. Of one, an orang, the President, the Rev. Dr. Haughton, has been a brilliant showman at a public lecture. The other a capybara, is the animal recently recommended as suitable for domestication by Irish cotters instead of the pig.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 2, 1885.

**THE VENOUS PULSE.**

It has long been a familiar fact that pulsation in certain of the larger veins of the body may be observed under particular conditions, and students are taught to recognise it in the great veins as they approach the right side of the heart. It is also a generally received opinion that the small veins do not exhibit the phenomenon of pulsation at all under ordinary circumstances, that form of it which is seen in inflammatory conditions being ascribed to the presence of unusual factors aiding its development. The normal pulsation of the small arteries is lost in the capillary plexus, and the absence of an irritable contractile coat in the latter and in the venous radicles has long been held to explain in great part why the propulsive force is wanting in them. If, however, the observations which have been published in the form of a letter to our contemporary, *Nature*, by Mr. J. Hippisley, should receive confirmation, it will be necessary that the views now generally current in this connection should receive modification, this writer having described a method of experimentation tending to prove that pulsation of at any rate moderate sized veins is a normal function of these structures. It is worthy of note that Mr. Hippisley prefaces the account of his observations by quoting from the article on the "Heart" contained in Rees' Encyclopædia (nearly fifty years old), and that his views both as to the forces of circulation and the

"obscurity" surrounding the return of blood to the heart, derived from this antiquated source of information, seems to be unilluminated by the light of modern discoveries and researches in physiology. But notwithstanding this shortcoming, the account he gives is not unworthy of attention, and the experimental proof he adduces in support of the theory of generalised venous pulsation is at once ingenious and simple. The fact itself is, according to the writer, apparent on close and careful inspection of the visible superficial veins—*e.g.*, on the back of the hand; and he finds that the pulsations so observed correspond alternately with the contraction and dilatation of the heart, and when contrasted with the pulse beats are found to be alternate and intermediate in relation to them. For the purpose of objective demonstration of the phenomenon, however, the following method is suggested:—A small piece of silvered glass, three-eighths of an inch by three-quarters, and with its silvered surface protected from damage by a thin paper gummed on it, is made to adhere to the surface of a swollen vein in such a manner that one edge of the glass rests on the central ridge of the vein, while the other is in contact with the surface clear of the visible vein beside it. This applied in the sunshine affords a spot of light, the movement of which reflected from the mirror indicates the slightest tilting of its plane by the undulating action of the vein. The light spot vibrates in accordance with the pulse, and its vibrations correspond in direction with the tilting which should be the result of the position of the mirror in relation to the vein. On applying a second mirror, further, to the *opposite* side of the vein, the vibrations of the light spot take an opposite direction as the result of a tilting anticlinal to the first; but a mirror placed on the knuckle, where veins of sensible importance are wanting, shows no appreciable vibration.

Such is the account given by our contemporary's correspondent, and it opens up a question of sufficient interest to engage serious attention, for if the appearances alleged can be easily made out by others and verified in all cases, there is suggested a possible explanation of a good many morbid conditions of the venous system, of which we know as yet but little more than the immediate results. Given that the veins of the lower extremity, for instance, assist the circulation of blood through them by regularly contracting on their contents, and it is not difficult to see how seriously prejudicial would be a loss of such power of control, with all its tendency to prevent such diseases as arise from sluggish circulation in this region, and the effects of which are so constantly manifested to the surgeon. Of the difficulties which arise to prevent an unconditional acceptance of the theory we need not now speak, they will occur at once to every one familiar with the anatomy and physiology of the structures in question; but these considerations ought not to be any hindrance to further investigations on the lines which Mr. Hippisley has indicated, and aided by the means of observation and by the skilled knowledge which can be brought to bear on the inquiry by practical physiologists.

THE President of the Medical Council has been sojourning at the Viceregal Lodge with the Lord Lieutenant, with whose family he is connected.

## DR. BRADLEY'S CASE.

THE questions raised by Mr. Lawson Tait in our last issue and by our other correspondents to-day as to the responsibility of Lord Coleridge and Sir William Harcourt for the most cruel and unjustifiable incarceration and detention of Dr. Bradley make it necessary for us to repudiate most emphatically all participation in an effort to palliate guilt or to relieve a guilty person of the just punishment of his offence. The impression may have been left on the minds of our readers by Mr. Lawson Tait's letter that the verdict with reference to Dr. Bradley is rather one of "Not proven" than "Not guilty," and that, as substantial evidence of his guilt was produced on his trial, Lord Coleridge and Sir William Harcourt could do no less than they did in the way of conviction, sentence, and punishment.

It is also hinted that it would be better for Dr. Bradley not to seek compensation, lest Parliamentary agitation to obtain it might bring to the front the evidence against him.

We cannot permit any such innuendos to pass in silence. We believe that Dr. Bradley is not partly, but wholly innocent, and that the only scrap of corroboration of the ridiculously improbable evidence of the prosecutrix was strongly coloured by professional rivalry and animosity towards Dr. Bradley, on which subject we wish to say as little as possible, because we believe that the author of the evidence is now heartily ashamed and sorry for it. We hold also that the evidence against Dr. Bradley was—as a whole—so weak that Lord Justice Coleridge would not have hanged a cat upon it, and that if he had, with proper judicial conscientiousness and impartiality, sifted it, he would have at once directed an acquittal instead of sending back—as he did that verdict to the jury to be turned into one of guilty. As to Sir William Harcourt's relation to the matter, it does not bear to be described as we could wish to characterise it. He, we believe, by his own act, or the act of his subordinates in the Home Office, calmly relieved himself of responsibility and trouble by giving the subject no consideration whatever. If he opened at all the memorials addressed to him it was to throw them into the waste-paper basket, and order that the usual hackneyed reply should be sent, and when Sir Richard Cross came into office we believe he found the matter in exactly the same state as on the day when poor Bradley was sent to gaol.

For these reasons we have clamoured for Dr. Bradley's release, and, if we hesitate to urge Parliamentary agitation to obtain compensation, we do so not at all because we doubt that such a demand would be reasonable and proper, but because we think it is a matter to be decided rather by Dr. Bradley than by us. No doubt, however, such an agitation might end, it would involve Dr. Bradley in an unpleasant notoriety; no doubt Sir Richard Cross would resist the necessity for publicly scrubbing Sir William Harcourt and Lord Coleridge by declaring Dr. Bradley to be absolutely innocent; no doubt the Treasury would resist, tooth and nail, the grant of one penny in compensation to any one; no doubt Sir William Harcourt and his supporters in the House would retaliate by trying to prove Dr. Bradley to

be clearly guilty; and no doubt a large section of the public would fall back on the proverb that there is "never smoke without fire," and would retain the suspicion that Dr. Bradley was half guilty.

In fact, it is very questionable whether Dr. Bradley and the profession could successfully fight Sir William Harcourt and Lord Coleridge in Parliament, and it is therefore doubtful whether it would be wise to open the attack.

But, nevertheless, we repeat our emphatic repudiation of all suggestions that Dr. Bradley is less than totally innocent, for if we thought that there was any ground for such insinuation he should have no support from this journal.

## CLOTHES IN THEIR RELATION TO HEALTH.

THE choice of materials for clothing has been dependant hitherto far more on the facilities which they offer for manufacture or self-decoration than on any preconceived idea of their suitability, although here as elsewhere, we find on examination that the consensus of opinion of succeeding generations generally leads in the right direction. The best method therefore of arriving at the truth is to reason backwards, and to endeavour to ascertain why certain materials have invariably been chosen under certain circumstances as clothing material, and this may enable us to understand the laws which underlie this apparent hazard in the matter of choice. The value of clothing consists, as we all know, in promoting the maintenance of our bodies at an equable temperature, and in shielding the surface from the effect of sudden and violent changes in the temperature of the surrounding atmosphere. Now, the value of any particular substance as an article of clothing is in inverse proportion to its capacity as a conductor of heat. But this is not the only quality to be considered in the selection of such materials, for while we wish to protect our bodies from undue loss of heat by radiation, we have to provide or allow for ventilation and the escape of watery vapour and gases, and here the materials vary within wide limits. It should be borne in mind that radiation takes place, not only in proportion to the relatively low temperature of the ambient air, but also, and more markedly, towards bodies which are possessed of a lower temperature than ourselves.

A great factor in protecting our bodies from thermometric changes lies in the different strata of air which intervene between the different layers or garments and permeate the fabrics themselves. It is to this that we owe the extreme warmth of such substances as eider down, or furs, or plumage of any sort, the interstices of each being filled with air, which is in itself a bad conductor of heat. Many experiments have been made since those first conducted by Rumford, in 1786, to determine the delays which occurred in the cooling of a thermometer heated to a certain degree when enveloped in hemp, flax, cotton, silk, and wool, respectively. Since this observer Senbier and Boeckmann have both recorded numerous experiments with a similar object in view. Black flannel was found to allow of the absorption and dispersion of heat more rapidly than lighter shades, but it is difficult to say how much of this is attributable to the difference in

the texture from the chemical changes involved in the dyeing. In any case, the differences found to exist between textures of various hues are only appreciable as regards solar heat, obscure heat not exhibiting the same preferences. In some more recent investigations by Pettenkofer on a cylinder of sheet iron filled with hot water and enveloped successively in different textures, the variations only represented some 1 or 2 per cent., and this irrespective of colour, but when the cylinder was exposed to the rays of the sun, the absorption of heat varied between linen and silk as much as 90 to 108. The effect of colour was even more striking, and was as follows:—White, 100; yellow, 140; green, 160; red, 168; blue (light), 198; black, 208. The figures readily explain why a black garment is unsuitable to wear in the sun. It is worthy of note that on enveloping the cylinder with a *double* layer of satin, cotton or fine linen, the loss of heat was only diminished by some 2 to 6 per cent.; whereas, with chamois leather, flannel or woollen cloths, the diminution amounted to from 20 to 30 per cent. The inference is evident, viz., that the resistance to the passage of heat depends less upon the individual conductivity of the textile fibres than upon the thickness, the volume and the texture of the materials. The conductivity of wadding for instance increases some 40 per cent. when strongly compressed. Although the radiation which goes on, is not notably diminished by doubling the thickness of the investing texture, if it be tightly drawn round the cylinder, it is quite otherwise if an air space is allowed to intervene between the two layers. With such an interspace of only one-third of an inch the radiation is diminished (exclusive of the diminution due to the layers themselves) to the extent of some 35 per cent. This, however, is based on the assumption that the intervening column of air is motionless, but as loose garments tend to favour the circulation of the air, they are, notwithstanding this fact, preferred in hot climates. The essential point indeed, is, that the greatest obstacle to the dissemination of heat, is found in a *discontinuity*, or want of homogeneity, in its elements. Heat, like sound, is but a form of molecular vibration, and is governed by the same laws. Then, again, the permeability of the various textures to air is a point of capital importance, and this varies from 1 in glazed kid to 100 in flannel. It is essential that our garments should allow of such ventilation, but it is also necessary that this should not take place so rapidly as to affect the sensory elements of the skin, hence the more slowly it takes place the more conducive it is to our health and comfort.

Another important property of textile fabrics is their capacity of absorbing and retaining moisture—the nearer the air is to its saturation point, the more moisture do they absorb owing to diminished evaporation. This is accentuated when the temperature, from any cause, falls. The water contained in textures may be divided into two categories, one part not appreciable to the feel and which cannot be squeezed out, the *hygrometric water* properly so-called, and a second part, which blocks the pores and which may be expelled by compression, the *interposed water*. According to the experiments of M. Coulvier, wool is more hygroscopic than hemp, and linen than cotton.

The quantity of water that these textures can absorb is much greater than is generally supposed. A woollen garment weighing 10 to 12 pounds will take up about a quart of water, to evaporate which completely will withdraw from the body from 5 to 600 units of heat. More moisture is absorbed at a low temperature than when it approaches 70 deg., further, since wet garments are better conductors of heat than dry ones, they protect us far less efficiently against the cold, hence the danger to health of damp and cold combined. This effect, however, is less marked in the case of woollen textures than in those of cotton, silk, or linen, and this is probably owing to the fact that, while the fibres of the latter all become softened on contact with water and so allow the pores of the tissue to become blocked, the fibres of wool, in virtue of their native elasticity, tend to keep the pores open and so favour evaporation, while the air contained in the pores checks to some extent undue radiation.

It has been remarked that vegetable fibre is less suited to purposes of clothing than substances which are of their very nature destined for this purpose. Take the fibres of flax or hemp, for example; they form an integral part of the plant, and are not called upon to possess any isolating or protective properties against cold. Now, as to cotton; this indeed serves to envelope the seed of a plant, and is, therefore, to some extent, protective; but silk, wool, eider-down, and fur, are, *par excellence*, the materials furnished by Nature for the express purpose of protection. As to the shape of our garments, they are now probably definitive in all essential particulars. Ladies' dress doubtless calls for reform, reasons of taste and æsthetics dominating too largely in their choice both of texture and of shape. One is apt to call to mind the profound and amusing speculations of Darwin on contemplating the rich plumage and often cumbersome ornamentation by means of which animals seek to place themselves in evidence, and so unconsciously aid in the designs of Nature in the matter of natural selection.

### Notes on Current Topics.

#### Another Fatal Mistake by a Druggist.

OUR American exchanges report another death arising through the mistake made by a chemist in substituting what is supposed to have been the corresponding morphia salt for hydrochlorate of quinine, which had been ordered. The victim, in this case was a little girl, three years old, and the daughter of a physician, who went himself to the store to procure the medicine. The child was suffering from a malarial attack, and her father decided to administer muriate of quinine as a remedy. Soon after the first dose of the mixture had been taken, however, the patient exhibited symptoms of opium poisoning, and notwithstanding every effort was made in her behalf, a fatal termination took place after several hours. At the time when the reports from which we quote were published, the official analysis of the stomach's contents had not been completed, but other evidence of the nature of the mistake made by the dispenser of the medicine was forthcoming. Thus, on examination of the drug store it was found that the place whence the assistant took the

bottle containing the substance he had put up was occupied by a bottle of hydrochlorate of morphia, and none of the quinine salt could be found in the place after diligent search. On these grounds the dispenser was committed for trial by the coroner's jury, pending the examination of the viscera.

#### The Congress Question.

THE controversy in regard to the Washington meeting of the International Medical Congress in 1887, has entered on a new phase by the publication in America of letters from Sir James Paget and Sir W. Maccormac, in both of which the writers expressly declare themselves in favour of the Congress meeting elsewhere than in Washington, unless an early modification of the existing state of things is brought about. Sir James Paget addressed his letter to Dr. Minis Hays, and as the immediate predecessor in the presidency of the Congress of the lamented Professor Panum, his observations are likely to be received. even by the unfamiliar crowd of office bearers at present nominated to posts in the next Congress, with attention, if not with respect. Sir James says decisively, "certainly it was not supposed that the Congress would be regulated, with any degree of exclusiveness, by the members of a Medical Association, however numerous; and I think it quite as certain that, if this had been thought possible, the proposal that the next meeting should be held in the United States would not have been adopted." Sir James further expresses his belief that, without the support of the eminent men who now hold aloof from the Congress the meeting cannot be a success; and though the proposition is too self-evident to need enforcing it is perhaps as well that so high an authority should have thus spoken. A meeting is to be held this month by the innovating section of the American Association, and it is to be hoped it may be sufficiently impressed with the mischief it has already done, to feel satisfied with the notoriety accruing from it, and agree to retire into that obscurity which is eminently becoming to its members, and out of which they have, this time at any rate, most unwisely emerged.

#### The River Lea.

FOR some time past inhabitants of the district watered by the River Lea in the metropolis have been loudly complaining of the filthy condition of the stream, which, being heavily charged with sewage from Tottenham and Enfield is, by the time it reaches Hackney, little better than a huge open sewer. Consequently, not only is it ruined for boating and pleasure purposes, but it is also a constant danger to the health of all who live within sight or smell of its foul condition. As a consequence public indignation has naturally found a voice, and demands have been made to the Lea Conservancy Board to take steps for the cessation of the nuisance. The whole question, however, resolves itself into one of the liability of the polluting towns, and especially of the worst offender, Tottenham, to remedy the ill created by the outflow of its sewage. Warnings to this effect have, it appears, hitherto been unheeded; but now the force of opinion is too strong to be resisted, and promise of increased sewage works is made by the authorities. But little benefit, however, is likely to arise out of this, so long as

the only efficient mode of dealing with large quantities of sewage is neglected for one reason or another. The success of the A B C process has been again and again demonstrated, and yet it seems impossible to persuade towns, or rather, the authorities in towns, to adopt it, notwithstanding the proved incapacity of other modes of treatment. Some time the purification of rivers will become a matter of popular concern, and the people will themselves see it that further trifling with a life and death problem is no longer tolerated in the interests of this, that, or the other advocate of a particular system; but that whatever plan will give the desired results shall be employed to advance the national health. So far the only process of purification which enables the passage of a clear and fairly pure effluent current of water in place of the hideous outflow now poured into our rivers after so-called purification of sewage by filtering and suspension, is the A B C process in use at Aylesbury, and the Lea riversiders will do wisely if they persist in their demand that either this shall be adopted in their interests, or that any other plan chosen in its stead shall produce results as favourable as it has been shown to do.

#### Recovery from Traumatic Tetanus.

A CASE of traumatic tetanus terminating in recovery after two weeks, is reported in the *New York Medical Record* by Dr. J. G. Starr of Monteiro. The patient was a woman who fell against an old corn cultivator and cut her hand near the thumb on the rusty corner of one of the ploughs of the machine. The wound was three fourths of an inch long, and one-eighth of an inch deep, and had nearly healed without suppuration three days after the accident. At this time the patient's left arm and jaw became stiff and painful, and paroxysms of pain and muscular spasm soon became general over the body. They lasted from one to two hours and recurred at intervals of from six to thirty-six hours. The temperature during the first week was 101 deg.; pulse 120 to 130 deg. In the second week the pulse rate was 90 to 100, and temperature varied from 99 deg. to 99½ deg. The treatment consisted in administration of bromide of potassium, chloral hydrate and fluid extract of physostigma, given in succession until their physiological effects were established. Sleep was induced by morphine as required. The wound was thoroughly cauterised with silver nitrate and nitric acid, and covered with a soft poultice; it was freely incised several times, and bled freely. A fly blister was applied along the whole extent of the spine, and ice was placed from time to time over the lower portion of the back. Cascara and calomel were given as occasion required.

#### Curious Cause of Obstruction to Breathing.

AN inquest was held on Friday last before Mr. Carttar, at Greenwich, respecting the death of a child aged fifteen months. The evidence of a woman in whose charge the child was left by its father, a marine engineer went to show that, while seated with her at the tea table deceased secured the head of a shrimp, and putting it into his mouth, succeeded, in spite of the woman's efforts to obtain it, in swallowing it. Soon afterwards symptoms of choking appeared, and the child was taken

to the Seamen's Hospital, where it died the same night. While in the institution evident signs of obstructed respiration were present, and an attempt to find and remove the foreign body was made by cutting down upon, and opening the trachea, but without result. Post-mortem, however, the shrimp's head was found at the bottom of the trachea, at the junction of the bronchi, and to its presence the death was attributed by the jury.

#### Who Owns the Prescription?

THIS question has been asked so many times that it is now in order to set it at rest as far as America is concerned. The Supreme Courts of Massachusetts and of New York have ruled as follows:—"The question before the Court seems to be very simple, indeed. A patient applies to a physician and receives from him certain advice, for which he tenders a fee. The physician hands a piece of paper to the patient, purporting to be a written order for certain goods, called drugs, which order is filled by a merchant or apothecary. The payment of the fee, and the delivery of the goods, or drugs, terminates the verbal contract, and the druggist keeps the prescription as evidence that the contract has been fulfilled as far as he is concerned. The druggist can, if he so please, on his own responsibility, renew the drugs, for he is but a merchant, and has a perfect right to sell drugs to any one and in any shape. He need not keep the prescription, nor is he bound to give a copy, but, should error occur, he has no protection in case of suit." From this it would appear that, according to American law, a prescription is but an order for drugs, and the delivery of the drugs settles the matter. This may be good law, but it looks like bad justice, for it seems to us that a prescription is only the written expression of advice given by the physician, for which the patient pays, and of which he is at liberty to avail himself for all time. This attempt to make money by charging for repetitions of prescriptions or medicine is neither reasonable nor honourable.

#### Iodoformium Absolutum.

THE Chemische Fabrik auf Aktien, Berlin (late E. Schering) has recently taken out a patent for the manufacture of iodoform by electrolysis, and has given the name of Iodoformium absolutum to the product.

The iodoform thus produced is absolutely pure; it is a mild smelling, silky, delicate, and soft scaly powder of a pure citron yellow colour. It can be easily reduced to a fine powder by trituration. It is no higher in price than ordinary iodoform, although iodoform as sent out now is a very different article in its physical properties from what it was a few years ago. There is still room for improvement, and those who are in the habit of using it much will welcome the advent of the new preparation.

DR. RÖEMER reports an ovariectomy upon a child 20 months old.

A GOLD medal has been awarded by the jury of the International Inventions Exhibition to Dr. J. Ward Cousins, of Southsea, for "highly ingenious surgical inventions."

#### Death from Lightning.

AT the last meeting of the Berliner Medizinische Gesellschaft, Dr. Liman gave some interesting particulars relating to the deaths of two men from lightning. In the case of the first the muscular wall of the heart was found to be perforated at the apex, the opening being irregular in shape, and about 2 cm. in diameter, and passing through both ventricles and the septum. In the second case, in which death evidently took place from asphyxia, the hair on the head and beard were found singed on the right side, from the chin downwards ran a line of singed, excoriated patches of cutis. Numerous small extravasations of blood were present on the serous covering of the heart, under the pleura were a number of punctiform hæmorrhages, and the lungs were filled with frothy blood. Herr Leyden, who had devoted much attention to the subject, thought death had not taken place in the first case from the injury to the heart, but from general shock.

#### A Co-Ordination Centre for the Heart.

LAST year Herr Schmey, in conjunction with Professor Kronecker, conducted an investigation that led to the conclusion that a heart centre existed in animals that regulated the rythmical beat of the heart, and which they denominated the "co-ordination centre for the musculature of the cardiac chambers." Since then Herr Schmey has continued his investigations, carrying them into the human subject. He lately brought his conclusions before the Berliner Physiologische Gesellschaft, to the effect that a co-ordination centre is present also in the human heart, and that it is by paralysis of this that sudden death is produced in chloroform narcosis. Along with other observers, as Snow, the Members of the English Chloroform Committee, Ratinoff, and others, he believes that death is caused by the employment of air over-charged with chloroform vapour, and that the remedy consists in the use of an apparatus that permits accurate measurement of the proportions of air and chloroform vapour. He has invented such an apparatus, simple in construction and working, the employment of which he recommends.

#### Extirpation of the Spleen in Rabbits.

PROFESSOR G. TIZZONI reports in the *Archivio per le Scienze Med.*, vol. viii., a large number of experiments on removal of the spleen in rabbits. He arrives at the conclusion that the effect of splenectomy in these animals is absolutely nil; they are as healthy as before the operation, and not a single function appears to be disturbed by the absence of the organ. It is notorious that a little knowledge is a dangerous thing, and we fear that the knowledge, not by any means new, that healthy animals do not necessarily succumb to removal of the healthy spleen has led superficial reasoners to the dangerous conclusion that the enlarged spleen may be removed with safety from leucocythæmic human beings. Some surgeons have put their visionary theories into practice with results disastrous to the individuals experimented on. Before going further in this direction would it not be better to enlarge our knowledge a little by getting at the essential nature of the len-

coxythemia that lies at the bottom of these cases of splenic enlargement? Perhaps a little extension of our knowledge would lead us to leave splenectomy to the experimental physiologist.

#### The New Issue of the British Pharmacopœia.

THE official notice of the publication of the new edition of the *British Pharmacopœia* appeared in the *Gazette* yesterday, September 1, and the issue of the work has commenced from the Medical Council Office (299 Oxford Street,) or from Messrs. Spottiswoode and Co., 54 Gracechurch Street.

#### The Divorce of Medicine and Pharmacy.

A MEDICAL contemporary says that the second edition of the *Belgian Pharmacopœia* has now been published, and a Royal decree promulgated concerning pharmaceutical chemists and medical men. Amongst the various provisions, "it is forbidden to medical practitioners, when they are not authorised to keep a drug-depôt, to interfere in any way, direct or indirect, with the preparation and sending out of medicines, with the single exception of those employed in the treatment of venereal affections, provided always that they have been prepared by a pharmaceutical chemist, and have affixed to them a special ticket, with which it is obligatory to furnish the customer." Practitioners who are authorised to supply medicines to their patients are forbidden to keep an open shop, and their medicines must be bought from a pharmaceutical chemist. On the other hand, chemists are not allowed to treat diseases in any way whatever, nor to prescribe or to administer medicines. They are not permitted to have more than one shop, and they are compelled to keep certain medicines and apparatus always at hand, and in good condition.

#### Campaign Honours.

CONSEQUENT on the present settlement of the Soudan campaign and the withdrawal of British troops therefrom, the official despatches of the Commander-in-Chief were gazetted last week, in which Lord Wolseley highly compliments the administration of the Medical Department of the campaign, under the direction of Deputy Surgeon-General O'Nial. His Lordship says, during his extensive experience "he has never seen the sick and wounded better cared for. The arrangements were good, and the medical officers worked with great zeal and untiring devotion to their duties. At Suakim, Deputy Surgeons-General Barnett and Hinde directed all medical matters with great credit to themselves and to their department." With the publication of these despatches Her Majesty's Government has given effect to the recommendations of the Commander-in-Chief, and has resolved on the following promotions:—To be made Commanders of the Most Honourable Order of the Bath, Military division—Deputy Surgeon-General Lithgow, M.D.; Deputy Surgeon-General Hinde; and Brigade-Surgeon Thornton, M.B. To be an Extra-Member of the Military division, or Knight Commander of the said Order—Director-General Crawford, M.D. Deputy Surgeon O'Nial is promoted to be Surgeon-General; Surgeon-Majors Waters, Will, and Harvey to be Brigade Surgeons; and

Surgeons Gallwey, Pratt, Briggs, and Allin to be Surgeon-Majors. Deputy Surgeon-General Barnett was also named for promotion, but has since deceased.

#### The Overpressure Controversy.

It is not often that an ostensibly respectable journal has to sup humiliation, publicly and copiously, as the *Spectator* had to do on Saturday last, when it was compelled to publish a letter from Dr. Crichton-Browne convicting it of having knowingly said what was directly untrue in a review of a Danish work on Overpressure. The attitude which the *Spectator* has adopted and maintained towards the medical profession throughout the overpressure controversy has not in any degree surprised us, for it might have been expected that a journal that gushes over the twitchings of a decapitated frog would be deaf to the cries of suffering children; but the discreditable position into which its rancour has betrayed it does certainly awaken wonder as well as commiseration. It was scarcely to have been anticipated that a highly superior journal that is for ever congratulating itself that it is not as other journals are should have been caught fibbing flagrantly, and has been ignominiously punished on the spot. Yet such is unhappily the case; and so audacious is the untruth that has been brought home to our contemporary that it is almost impossible to avoid the conclusion that this is not its first offence. Presuming, we suppose, on the indisposition of authors to meddle with their critics, even when they are very far wrong, it repeated the misrepresentation which was put in circulation last year, and was then contradicted, that Dr. Crichton-Browne's report on "Over-pressure in Schools" was an officious and spontaneous production which was violently thrust upon the mild and unsuspecting Mundella, very much against his will. But it miscalculated the endurance of Dr. Crichton-Browne, who has promptly turned upon it and compelled it to eat its leek with what grace it could muster. With an extract from *Hansard* containing Mr. Mundella's intimation to the House of Commons that he had invited Dr. Crichton-Browne to report to him, held up before it, it admits that it was "mistaken." But this is not a question of mistake, but of mendacity, for the accusation is that the reviewer made his untrue statement knowing the real facts, and no one can question that the charge has been fully proved. Our contemporary is abject, but we fear unreformed, for in its note to Dr. Crichton-Browne's scathing letter, it performs a wriggling movement which might be called mendacious. Endeavouring to show that if it was wrong on one point, it was right on another, it argues that the report referred to was really unchecked, because Mr. Fitch's little memorandum was not written until after it was finished, thus ignoring the fact mentioned in Dr. Crichton-Browne's letter that Mr. Fitch accompanied him on some of his visits to schools, and had opportunities of checking his observations while they were being made. "Among the various causes which have conspired," says Dugald Stewart, "to relax our principles of veracity, the facility which the press affords us in modern times in addressing the world by means of anonymous publications is probably one of the most powerful." And an illustration of the correctness of

Dugald Stewart's remark is afforded by the deplorable backsliding of the *Spectator*. Had the review on the Danish work on over-pressure been sanctioned by the name of its author it would not have contained the misrepresentations to which exception has been taken. Tempted by the dangerous facility of anonymity, the author has permitted his principles of veracity to become relaxed, and we can only hope that the fate that has befallen him will be a warning to others of his class.

THE Youghal Board of Guardians have passed a resolution to reduce by 25 per cent. the salaries of the clerk of the union and medical officers and master of the work-houses.

SURGEON MAJOR KEATINGE has been appointed Principal Medical Officer of the Egyptian Army in Upper Egypt, and has left Cairo for Assouan to assume that position.

LAST year the number of medical and pharmaceutical students who completed their curriculum at the Universities of Spain was 703, the total number of students graduating being 3,598.

It is recorded in the Bombay Season Reports that on the 27th of last December, seven shepherds lost their lives at Athni, in the Belgaum district, through being struck by hailstones of the size of a cocoanut (!).

THE Secretary of State for War has sanctioned the payment of a gratuity of six months' pay to Surgeon J. Magill, M.D., Coldstream Guards, in consideration of the wound he received in action at Abu Klea on Jan. 17, when he was in charge of the Guards Division of the Camel Corps.

## Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

EDINBURGH.—HEALTH OF THE CITY.—The mortality in Edinburgh for the week ending with Saturday, the 22nd ult., was 72, and the death-rate 15 per 1,000. There were 15 deaths under one year, and 20 above sixty years, of which 2 were above eighty years. Diseases of the chest accounted for at least 25 deaths, and zymotic causes for 2, of which 1 was due to fever and 1 to diphtheria. The intimations of the week comprised fever 14, diphtheria 4, scarlatina 19, and measles 19.

GLASGOW DEATH-RATE.—The mortality in Glasgow for the week ending with Saturday, the 22nd ult., was at the rate of 21 per 1,000 per annum of the population. The previous week it was 26; and in the corresponding weeks of 1884, 1883, and 1882 the rates were 26, 25, and 20 respectively.

THE REGISTRAR-GENERAL'S RETURNS.—The weekly return of births, deaths, and marriages shows that the death-rate in the eight principal towns of Scotland during the week ending with Saturday, Aug. 22, 1885, was 19.6 per 1,000 of estimated population. This rate is 1.1 below that for the corresponding week of last year, and 0.8 below that for the previous week of the present year. The lowest mortality was recorded in Leith, viz., 11.4 per 1,000, and the

highest in Paisley, viz., 31.7 per 1,000. The mortality from the seven most familiar zymotic disease was at the rate of 9.3 per 1,000, or 1.5 below last week. Acute diseases of the chest caused 51 deaths, the number for the previous week being 43. The mean temperature was 57°·1, being 3°·1 above that for the week immediately preceding, but 5°·2 below that for the corresponding week of 1884.

CHARITABLE BEQUESTS IN GLASGOW.—The late Mr James Stevenson, Sandyford Place, Glasgow, has left the following charitable bequests:—The Royal Infirmary, £500; the Western Infirmary, £500; the Deaf and Dumb Institution, £300; the Asylum for the Blind, £300; and the Old Man's Friend Society and Aged Women's Home, £300.

THE ADMINISTRATION OF NARCOTICS TO CHILDREN OF TENDER AGE.—On the 25th ult., in Hamilton Sheriff Criminal Court, William Cooper was tried, before Sheriff Birnie and a jury, on a charge of culpable homicide, as also reckless and culpable administration of laudanum to a child of tender age. The charges were spoken to by two neighbours, who united in testifying that the child was pained and crying all the Friday night, and that it was found by them in a state of insensibility on Saturday, while they heard the accused state to the doctor that he had at four o'clock on Saturday morning, to soothe the pain, given it four drops of laudanum. It died next morning about four o'clock. The witnesses testified to the distress of mind shown by him after he had discovered his error. The first of the witnesses said she had used laudanum, but never heard of a child of five weeks getting four drops. She understood the scale was a drop for each year. The other thought it was a drop for each week. Dr. Crawford, Uddingston, stated that he visited the child at 10.30 a.m. on Saturday, and was frequently there up till 2 on Sunday morning. He was of opinion that it died from the effects of laudanum or other narcotic poison. In cross-examination, the doctor said the accused manifested great anxiety in the case, and followed out all his directions, and so far as he saw, his error was one of judgment and not of intention. Soothing syrups and other patent medicines of the same class were largely composed of morphia or laudanum, and fatal results often attended their use. The Sheriff—Would you think it a good thing to give soothing syrup or suchlike compositions to a child of this age?—A. As a medical man, I would think it a very bad thing. Q. At what age is it safe to give soothing syrup to a child?—A. I do not think it safe almost at any age under a year old. He should say other homœopathic medicines in bottles were also unsafe for mothers to give to children under a year old. The Sheriff having summed up, the jury, after a minute's absence, returned a verdict of not guilty.

## Correspondence.

### DR. BRADLEY'S CASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Bradley's friends are, I am sure, deeply grateful to Mr. Lawson Tait for his exertions on behalf of this much-injured gentleman; but I think, Sir, that you will agree with me that my friend Mr. Tait has not been well advised in coming forward (*Medical Press*, Aug. 19) on behalf of Lord Coleridge and the Home Secretaries just now, when the question of compensation to Dr. Bradley is still *sub judice*.

In my letter which appeared in your number of the 29th July I took care to avoid any allusion to Lord Coleridge; and allow me to ask how it is that Mr. Tait has overlooked the letter of Sir Joseph McKenna and your stern leading article upon it in your number of July 1st. We cannot ask Mr. Tait to make public use of the Judge's notes; but I venture

to challenge him as a medical man and a man of the world to point out a single statement by any one of the witnesses which confirms in any manner whatever the insane story of the prosecutrix, and which it is clear that the jury put no faith in.

Further, why did Sir R. Cross state in the House of Commons that he had referred the matter to the Lord Chancellor? Why was Lord Chief Justice Coleridge not consulted?

Yours, &c.,

EWING WHITTLE, M.D.

Parliament Terrace, Liverpool.

Law does not always mean justice, and Mr. Tait's remarks on this subject are true and to the point.

I trust that the fund being raised will receive generous support, and that whatever amends we can make to Dr. Bradley in a pecuniary sense for all that he has suffered may be worthy of the profession at large. It is truly a case to do as each member would have another act towards himself were the case his own. Mr. Lawson Tait has himself acted most generously in the matter.

Yours, &c.,

JOHN W. MARTIN, M.D.

76 Brunswick Street, Sheffield.

#### TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Any assurance of Mr. Lawson Tait's as to the absence of prejudice or indifference on the part of Lord Coleridge or Sir Wm. Harcourt in connection with Dr. Bradley's case should be received with the greatest respect, and whilst accepting it in the spirit given, I, for my own part, and I am sure others, would be greatly pleased if he can give a fuller explanation of the neglect with which the promptly presented petitions from the inhabitants of Brimington and the neighbourhood of Chesterfield, and from the members of the profession, which was truly remarkable for its representative character, were received. Seven months of torture to Dr. Bradley appear to have been allowed to pass, by both Judge and Home Secretary, without the smallest effort being made to give him relief; whilst within a month of the new Secretary's advent to office our suffering *confrère* is released. Was the Judge satisfied himself as to the justice of the verdict and the sentence? How could he or Sir William Harcourt read, without taking immediate action, the strongly-worded petition from the profession? These are points which require a fuller explanation. The answer received to these petitions was that Sir Wm. Harcourt *sans raison to interfere*. I feel still convinced that, no matter what the medical evidence was upon which Dr. Bradley was convicted, this conduct on the part of Sir Wm. Harcourt was, to say the least of it, insulting to a highly representative body of medical men. Their strong expression of opinion ought to have outweighed the unimportant evidence of one medical man, who himself states that, had he been cross-examined, a very different complexion would have been placed upon his evidence, and whose evidence as a whole was negative rather than positive. I know no case more thoroughly representative of the dangers to which medical men are exposed in the practice of their profession in dealing with female patients, and were such cases and such charges allowed to go unchallenged, it would be perfectly impossible for medical men to do their duty in dealing with hysterical or epileptic women. As a man of the world, as an educated man, and as one trained in the sifting of evidence, I still contend that Lord Coleridge ought to have been alive to the impossibilities and absurdities of the case; and, when the opening was given him to undo the mischief done, by the strongly expressed opinion of representative medical men, any one of whom, had they been called upon as experts to give evidence at the trial, would have made a conviction impossible, he ought eagerly to have grasped at the opportunity, and shown the profession that he was anxious to make amends to a deeply injured man. Does he or Sir William Harcourt realise the full horror of Dr. Bradley's position, or the ruin brought upon him? Were the tables turned, possibly their eyes might have been opened to the cruelty of inaction and indifference, and they might have desired some sign of interest and consideration from those responsible for their continued incarceration. The evidence and the petitions remained the same for the one month as for the seven. What blinded Sir Wm. Harcourt to the insufficiency of the evidence, to put it mildly, which was so clear to Sir Richard Cross? If Mr. Tait can give a fuller explanation on this point as to the cause of delay I shall be only too pleased to retract every word of suspicion I may have spoken or written, and do full justice to Sir Wm. Harcourt and Lord Coleridge's justice and impartiality in what has been certainly one of the most cruel cases of suffering and of a ruined career that has ever come under my notice—a case that arouses feelings of the deepest and bitterest indignation to think that such things are possible.

It was of course a mistake of Dr. Bradley to rely upon his innocence, but, to men with small means it is not always easy to incur the expenses necessary for a proper defence.

#### MEDICAL MEN AS VOTERS.

##### TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your pronouncement as above in the late issue of your journal, though apparently penned to support the claims of Mr. Erichsen to a seat in the Commons, deserves the close attention of the profession at large; for it comes *à propos* with a number of questions of vital importance, which, if ever raised, have certainly been never answered, and never as much as properly ventilated. But, if your present call be responded to, you and the respondents, the despised and ill-used atoms of the element Medicine, ought to attain to a currency and lustre equal to that of those current and useful, social and professional elements, Divinity and Law. The professors of medicine as such have little to thank the members of any party—Whig, Tory, Radical, Nationalist, or Independent—for anything in the shape of right, much less gratuity or favour, which they have obtained heretofore from State or Government. And, if they have not obtained places as honourable and profitable as their outlay and education demanded, it was solely because they lived in an attitude of cringing servility and expectancy towards political parties, and because those parties found it a profitable game to wheedle them into a perpetuation of this prayerful and imploring attitude instead of giving them a box on the ear and ordering them to put their shoulders to the wheel as Hercules did with the pious, supplicating, and lazy waggoner.

Therefore, had you extended the terms of your admonition and call to duty so as to include candidates for the new Parliament as well as voters, I think that the profession at large ought to thank you for the call, and to support vigorously by pen, tongue, and pocket the medical men who would aspire to the dignity and responsibility of members of the new Parliament. For, while every art, industry, trade, profession, or occupation in the country has been fully and oftentimes superabundantly represented in the Imperial Parliament, Medicine alone stood shivering and whining in the cold, appealing in vain to the charity or compassion of its liberal fellow-citizens. And therefore it is that such scandalous miscarriages of justice as the late Sweetmore-Bradley-Coleridge-Harcourt case have been possible of fulfilment.

The Parliament now on its death-bed has been remarkable for its statutes remedial as well as penal and prohibitory; but the work of a Parliament has been most imperfectly performed by it nevertheless. The Criminal Law Amendment Act was no doubt a necessary remedy for a necessary evil, but a Court of Criminal Appeal had its demands too, and they are still unsatisfied, as this case of Dr. Bradley's and others can testify. I am, Sir, yours, &c.,

J. O'FLANAGAN.

Houghton-le-Spring, Aug. 27th, 1885.

##### TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Hitherto, I think wisely, medical journals have abstained from taking any part in the political ventures of medical men. I think this has been a wise position. Medical men are not generally active politicians—at least, those who are in practice. Now, I find, as a member of the British Medical Association, that the *Journal* of that Association is made a means of advancing Mr. Erichsen's claims and of putting that gentleman's views, as a *Liberal*, before those members of the constituency he desires to represent who are readers of the *Journal* in question. No one holds Mr. Erichsen, as a surgeon and surgical writer, in higher repute than I do, but I protest most emphatically against the *Journal* of the British Medical Association being made directly or indirectly, a political medium of expression of

candidates' views, be they Conservative, Liberal, or Radical, or its pages by a sort of side wind being occupied by the political views or addresses of any candidate, no matter how distinguished. In view of the coming General Election I think this rule should be strictly adhered to. It is well known that prominent among the powers that be in the Association are some strong Radical luminaries and expectant recipients of Parliamentary honours. I do not for obvious reasons write this letter to the Association *Journal*. But I trust that it may rouse indirectly the zealous watchfulness of members of the Association in order that its *Journal* may be kept for the purposes of the Association, and in no way be used as a political organ. I write this letter free of all political bias, and would just as freely condemn any efforts to introduce by headings and paragraphs the virtues of Tory candidates into the *Journal* of the Association.

Yours, &c.,

London, Aug. 20.

M. B. M. A.

We cordially acquiesce in our correspondent's opinion that a medical journal should have no general politics, but we altogether dissent from the old-fashioned proposition that medical practitioners should have no political opinions of their own, and we hold that a medical journal ought to urge its readers to support an eligible medical candidate irrespective of his Toryism, Liberalism, or Radicalism.

**The British Dental Association.**—This Association held its fifth annual general meeting at Cambridge on Thursday, Friday, and Saturday last, under the presidency of Mr. Richard White, L.D.S. Eng., of Norwich. The members present, about one hundred and fifty in number, included Sir Edwin Saunders, Mr. John Tomes, F.R.S., Dr. John Smith, President of the Royal College of Surgeons of Edinburgh, and President of the Association during the past year, Mr. C. Spence Bate, F.R.S., of Plymouth, Professor Stack, of Dublin, and representatives from all parts of the United Kingdom. The meetings were held in the large hall of the Union Society, which most liberally placed the whole of its commodious premises at the disposal of the Association. At the business meeting, held on Thursday morning, the Treasurer reported a balance in hand of over £600, and the Hon. Secretary, the election of some fifty new members during the past year. It was decided that the next annual meeting should be held in London on August 19th, 20th, and 21st, 1886, under the presidency of Sir Edwin Saunders. The retiring President (Dr. John Smith, of Edinburgh) then delivered his valedictory address, in which he deprecated interference on the part of the Association, as far as possible, with the horde of irregular practitioners who prey upon the public, since the latter was apt to look upon such prosecutions rather as persecutions, and had usually only itself to blame for what it suffered at the hands of such pretenders. Mr. R. White, the President-elect, afterwards delivered his inaugural address, which was devoted to a consideration of the educational, social, political, and scientific prospects of the dental profession. Thursday and Friday afternoons were devoted to the reading and discussion of papers on subjects of professional interest, whilst Friday morning was occupied with practical demonstrations of various operations in dental surgery and technical processes. Different methods of filling teeth with gold were shown by Messrs. Storer Bennett, of London, Cooke Parsons, of Clifton, J. J. Andrew, of Belfast, Balkwill, of Plymouth, and A. Jones, jun., of Cambridge; whilst other operations in dentistry were exhibited by Messrs. N. Pedley, of London, Verrior, of Weymouth, Bogue, of New York, Cunningham, of Cambridge, &c. There were also on view interesting collections of pathological specimens contributed by members of the profession, and of instruments and appliances sent by well-known makers. The usual social element of such gatherings was not absent, the programme including a *conversazione* at Peterhouse, a garden party at Downing, and a dinner in the hall of Caius College. On Saturday a large party of members and friends took part in an excursion up the Cam to Clayhith, followed by a visit to the cathedral city of Ely. Thanks to the admirable arrangements of the local committee, and especially of the local secretaries, Messrs. Cunningham and Rhodes, the meeting passed off most successfully and pleasantly, notwithstanding the ungenial state of the weather.

## Literary Notes and Gossip.

THE Empress Augusta of Austria has offered a prize of eight hundred dollars for the best portable hospital or sick-room tent for use in time of war and during epidemics. The premium will be awarded in connection with the Antwerp Exhibition.

WE are promised this month the "Life of Sir Robert Christison, Bart., M.D., D.C.L." An autobiography edited by his sons. Such a work will possess interest above the common for the profession, inasmuch as few occupied a more prominent position in it during the last half century of medical education and reform than the illustrious Edinburgh professor.

HIRSCHWALD, of Berlin, announces the publication of a third edition of R. Liebreich's "Atlas of Ophthalmoscopy." "Darstellung des Augengrunds un Gesunden und Kranken Zustande." Price, 32 m. "A Handbook of the Surgical Diseases of the Ear," by H. Schwarze, is announced by Enke, of Stuttgart.

A WRITER in an American contemporary, the *New England Medical Monthly*, deploras the debasement of the literature of circulars by the names and addresses of prominent New York physicians which are now printed on carpenter's and plumber's circulars as advertisements. Since literary enterprise has stooped to tradesmen's handbills, we would suggest as the next step—their tools.

THE death is announced, at the ripe age of 82, of Mr. Thoms, F.S.A., the projector and for many years editor of *Notes and Queries*. Deceased began life in the office of Chelsea Hospital, and became an author of repute almost before he was out of his teens. For years he held the post of Librarian to the House of Lords, which he resigned in consequence of advanced age. Mr. Thoms is succeeded in the editorial chair of *Notes and Queries* by Dr. John Deran.

DR. G. L. AUSTIN, of Boston, U.S.A., has written a book, and having, doubtless, some misgivings as to its success, solicited the services of Mrs. Mary Livermore before casting it on the perfidious waters of public opinion. That lady, whose commendatory epistle prefaces the said book, is good enough to be "especially thankful to Dr. Austin for his disparaging words concerning the unclean army of gynecologists." She "regards these specialists as a pestiferous set, and the bare mention of them is the same in its effect upon her as a red rag to a bull." What have American gynecologists been doing to this estimable lady?

MR. J. BRINDLEY JAMES has arrived at the conclusion that "it has been reserved for modern scientific investigation to demonstrate that in certain persons' mind, sensation and volition can be thoroughly controlled by the suggestive ideas of another individual." Well, perhaps it is so; but if it is, then history is a fable, and Mr. James is a discoverer of the first magnitude. We still think, however, that history does not err, and feel convinced that Shakespeare, not to mention earlier writers, has "demonstrated that," &c. "The Influence of the Mind over the Body" is the title of the paper in which Mr. James develops his theories; it is very entertaining.

TWO papers on cholera have been recently published—one from the pen of Professor Burdon Sanderson, based on the lecture he recently delivered before the Royal Institution; the other by Dr. Cameron, M.P. Professor Sanderson considers cholera, like other epidemic diseases, owes its power of spreading to a living and self-multiplying organism, though he hesitates to admit that Koch's comma bacillus is the specific organism. The liability of a locality to attacks of cholera depends on the physical character of the soil, and certain changes which it undergoes in the course of the seasons; but no combination of soil and season will produce a harvest unless the seed has been sown. Dr. Cameron accepts the bacillary hypothesis, and contends that Dr. Ferran's inoculations have done as much to prevent cholera as vaccination has to prevent small-pox!

THE Spanish inventor of cholera vaccine seems to have successfully qualified himself to occupy a prominent place in that part of the temple of fame reserved for impudent quacks. That his whole system is one magnified imposture is now pretty generally conceded, and his offer to put his services at the disposal of the Marseilles authorities—at what price was not mentioned—has very properly been rejected. One cannot, however, help a certain amount of admiration for the man's unblushing effrontery, nor is it possible to forget his naïve remark to the effect that it paid him better to coin money by so-called vaccination with a secretly-prepared fluid than to give his secret to the world, trusting to national gratitude for his reward. As it is, he must have netted at least fifty thousand pounds by his proceedings.

WHAT discoverers have to expect when they give their secrets to mankind has always been pretty well understood, and Ferran might have had the example of Dr. Warburg in his mind when he refused to give up his mixture without first receiving the promise of a reward. The inventor of Warburg's tincture revealed the formula of his priceless creation, trusting to the generosity of mankind to show a due appreciation of the boon he thus conferred upon suffering humanity, and now in his old age he is barely able to supply himself with the necessaries of life. Can we wonder that men are chary of courting fame at the expense of bread when such examples are ever before their eyes?

AT the time of their delivery in January last, we drew attention to the admirable series of "Cantor" Lectures which Dr. G. V. Poore had undertaken to address to the Society of Arts. The subject of the three discourses was "Climate in its Relation to Health," and they embodied an amount of practical information so eminently useful to medical men that the interest they awoke in the profession was easily understood. We are glad to find that Dr. Poore has now issued the lectures in a collected form, and thus made them more generally available than when they existed only in the buried leaves of a periodical. The wide circulation of the pamphlet would be attended with much benefit in every way, and people on the look-out for another abiding place for health's sake will especially gain by its perusal.

SOME six thousand feet above sea level, situated on a beautiful plateau in the Upper Engadine, there has been recently erected a magnificent hotel—*Kursaal de la Maloja*—for the purposes of amusement and instruction of the numerous visitors who reside or pass through the Maloja. Dr. Wise, the resident physician, has started a newspaper, which, as evidencing the varied capacities of the said hotel and its staff, is a highly creditable production. Few hotels can boast of an editor and printing establishment within its walls, and we hope the enterprise will be rewarded with the success it deserves. Already we hear good accounts of the Maloja district as rivalling even St. Moritz, and more than one member of the profession who has passed thither during the present season speaks very highly of the locality and of the hotel, with which the journal here referred to is connected.

THE authorities of the Chelsea Hospital for Women have resolved to raise a memorial to the late Sir Moses Montefiore by collecting a sum of £1,500 wherewith to name a ward in memory of the deceased philanthropist and endow a bed in his name. Practically the object is to pay off a portion of the debt under which the hospital labours, and the decease of its late centenarian governor offers a fitting opportunity for appealing to the charity of the public. It cannot be denied that the conversion of a ward of the hospital specially to the service of Jewesses will be a great boon to the Hebrew community in London, since there is no hospital specially devoted to the diseases of women in which such wards exist, although the London Hospital freely admits Jewish women so affected into its Hebrew ward. The object of the Montefiore memorial fund is a good one, and we trust it may succeed.

IN the new edition of Mr. Alder Smith's useful little treatise on "Ringworm; its Diagnosis and Treatment" (London: H. K. Lewis), a good deal of fresh matter has been added. The subjects of diagnosis and of treatment have been practically rewritten, while other portions have been enriched. A short sketch of the history of the disease and a reference to the latest researches has been prefixed. A fifth plate of considerable beauty has been added to those

already published, showing the mycelium and conidia on a stump from chronic ringworm. The armamentarium for treatment has been increased by the introduction of the pure oleates of coffee and mercury, as originally recommended by Dr. Shoemaker in the oculus of this journal, and other drugs. We cannot speak too highly of the excellent arrangement of the whole. We anticipate for the work an even greater measure of success than the two former editions have had.

THE appearance of the third edition of Dr. George Oliver's convenient little bedside companion, on "Bedside Urine Testing" (London: Lewis), is the best evidence of its success. The principle of the author is portability. The completest system of urine analysis is, for the ordinary purposes of the clinician, of little value, unless it be adaptable to the cramped space in which he has, of necessity, sometimes to work. The introduction of test-papers was, therefore, a considerable advance on more cumbersome methods, and if the possibilities predicted of them had proved correct, nothing more could have been desired. But, while admitting their value, from clinical experience we are not quite satisfied of their entire accuracy. Still, in ordinary practice, the chances of error are comparatively slight, and the readiness with which the test can be applied will probably ensure their being used, when otherwise full examination of the urine would have been omitted. In this edition several chapters have been added, and the worth of the work much enhanced by the record of results obtained by the author during the past twelve months. The book is pleasantly written and well got up.

A SECOND edition of Lee's "Lectures on Children's Diseases" (Baillière, Tindall, and Cox), is now before us, the first we understand having been exhausted in a couple of months. The lectures comprised in this unpretending little volume, the majority of which originally appeared in these columns, embrace within their limits a not inconsiderable number of children's diseases, and amongst them many of the most important ones. From the practitioner's point of view those diseases may be considered the most frequently met with, or those which are the most difficult to treat successfully. Few will deny that rickets, diseases of the skin, whooping-cough, diarrhæa, syphilis, enlarged glands, and ulcerations of the skin, which are amongst the subjects treated of, may be classed under one or the other category. The lectures reveal an acuteness of perception, extensive reading, and breadth of thought, and thus show themselves the work of an accomplished physician. To the practitioner they are better than systematic, they are eminently practical, and as such will well repay careful study. The writer has had an immense field for observation, and made use of it to good purpose, so that on subjects on which he has arrived at definite conclusions, and he has done so in many, what he says is worthy of thoughtful consideration. We can heartily recommend the lectures to all interested in children's diseases, whether students, or junior or older practitioners.

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, July 29:—Contributions to Pathology and the Practice of Medicine, by J. R. Wardell, M.D. Ed. The Saline Waters of Leamington, by F. W. Smith, M.D. (2nd edit.) Cholera Curable, by John Chapman, M.D. Unbelief, by Maurice C. Hime, LL.D. Sanitary Suggestions, by Sampson Low, B.A. The Climate of Llandudno, by Jas. Nichol, M.D. Diseases of the Kidneys and Urinary Derangements, by C. H. Ralfe, M.D. Cantab. Proceedings of the Liverpool Medical Institution, Vol. IX.

SURGEON-GENERAL T. W. FOX, principal medical officer on the staff of General Stephenson, commanding the army of occupation in Egypt, has been selected for staff service in India.

THE Deputy Coroner for Westminster refused, at an inquest held on Monday, to receive a rider of censure on the medical authorities of St. George's Hospital, because it was against the weight of evidence. The coroner is not a medical man, and we the more cordially thank him for his defence of the profession.

## Notices to Correspondents.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**READING CASES.**—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, may now be had a either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

**LOCAL REPORTS AND NEWS.**—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

**FLUOR (Manchester).**—Not at all; the discrepancy in analyses has been discovered and adjusted in the last edition.

**MR. THOMAS (Neath).**—We would not advocate the claims of Mr. Erichsen or any other candidate for his politics, but on principle, because he is a medical man. As medical journalists, we have nothing to do with the politics of any candidate except if his avowed principles are opposed to the interests of our common profession, in which case we should use every influence in our power to destroy his chances.

**A THIRD YEAR'S MAN.**—A new edition is, we hear, in active preparation. The announcement of a definite time for publication is not yet made.

**DR. GRIGG (Mayfair).**—Having given space to both sides of the controversy in our issue for August 19th, and, moreover, as the correspondent concerned is abroad (travelling), we do not think it desirable to re-open the question.

**DR. BARBER.**—No one of the scientific experts who have been in communication with Dr. Ferran respecting the latter's pretended discovery has expressed himself in any way satisfied with the results of the inquiry. Two of the most eminent—Dr. Brouardel, of Paris, and Dr. Von Ermengem, of Brussels—are both disgusted with the palpable pretensions of the Spanish physician, and show that they are so very plainly by their expressed ridicule of the methods and knowledge peculiar to Ferran. There can no longer be any doubt that the man is a mere impostor.

### THE BRADLEY FUND.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I enclose a further list of subscriptions, which I shall be glad if you will kindly publish in the next issue of your journal.

I remain, Sir, yours faithfully,

RICHARD JEFFREYS.

Eastwood House, Chesterfield, Aug. 26th, 1885.

Sir Prescott Hewett, Bt. .. £10 10 0	Mr. G. B. Morgan .. £1 1 0

**MR. DENTON.**—Any information likely to be of general service to our readers will be welcomed. Judging from the outline there seems a probability that it will be extremely useful. You had better write.

**DR. FEARNLEY.**—Not as regards the knee-joint. Amputation gives infinitely more encouraging results.

**DR. W. C. (West Kensington).**—1. It is against our rule, except in a matter of urgency, to insert letters which have already appeared in a contemporary. 2. The gentleman personally addressed is abroad; he will see your letter on his return.

**DR. PEARSE (Plymouth).**—Letter crowded out at press; will appear in our next.

**SURGEON AND AGENT.**—Legally there is no such allowance. Anything of the kind is in the nature of a gratuity, and, as such, optional.

**MR. BAILEY (Ramsgate).**—The history of the case decidedly suggests that the growth is malignant. It would, however, be advisable to puncture it as a preliminary diagnostic measure. The usual duration is two years, but this time may, of course, be exceeded or shortened considerably.

## Vacancies.

**Birmingham General Dispensary.**—Resident Surgeon. Salary, £150 per annum, with furnished rooms, &c. Applications, with testimonials, to the Secretary, on or before September 22.

**Bristol General Hospital.**—Physician's Assistant. Salary, £50 per annum, with board, &c. Applications to the Secretary, on or before September 9.

**Coventry and Warwickshire Hospital.**—House Surgeon. Salary, £100 per annum, with board, lodging, &c. Applications to the Secretary on or before September 10.

**Ebbw Vale, Monmouthshire.**—Surgeon (married) to take charge of an Ironworks and Colliery District. Salary, £550 per annum. Applications, with testimonials, to W. Dayson, Secretary, Doctors' Fund Committee, Ebbw Vale, Mon., on or before September 30.

**Granard Union, Finnea Dispensary.**—Medical Officer. Salary, £116 and fees. Election September 9.

**Kent County Lunatic Asylum.**—Assistant Medical Officer. Salary, £120 per annum, with furnished apartments, &c. Application, with testimonials, to the Clerk to the Committee of Visitors, on or before September 10.

**Leeds.**—General Infirmary.—Resident Obstetric Officer. Salary, £100 per annum, with board and residence. Applications to Mr. Blair, General Manager, before September 10.

**Manchester Royal Infirmary.**—Resident Surgical Officer. Salary, £150 per annum, with board and residence. Applications, with testimonials, to the Chairman of the Board, on or before Sept. 12.

**Newport Infirmary and Dispensary.**—House Surgeon. Salary £100 per annum, with board, &c. Applications, with testimonials, to the Secretary not later than September 12.

**Pontefract General Dispensary, Yorkshire.**—Resident Medical Officer. Salary, £180 per annum, with furnished rooms, &c. Applications, with testimonials, to G. St. J. Oldham, Esq., The Dispensary, Pontefract, on or before September 8.

**Preston and County of Lancaster Royal Infirmary.**—Senior House Surgeon. Salary, £100 per annum, with board, &c. Applications, with testimonials, to the Secretary, on or before September 11.

## Appointments.

**DOW, W. O., M.B., C.M.Ed.,** House Surgeon to the Ayr County Hospital, EVANS, R., L.R.C.P. Ed., M.R.C.S., Assistant Medical Officer to the Workhouse and Infirmary, Hackney Union.

**GORDON, W. S., M.B., B.Ch. Dub.,** Resident Medical Officer for the District Lunatic Asylum, Mullingar.

**KING, J. C., L.R.C.P. Ed., L.R.C.S. Ed.,** Medical Officer to the Castlepollard Dispensary, co. Westmeath.

**MCCLURE, H., M.D., M.Ch. Q.U.I.,** Medical Officer for the Cromer District of the Erpingham Union.

**MAJOR, H. C., M.D., C.M.Ed.,** Honorary Medical Officer to the Bradford Fever Hospital.

**MEARS, R., L.R.C.P. Ed., M.R.C.S.,** Medical Officer for the Atherstone District and Workhouse, Atherstone Union.

**OWEN, D. C. L., F.R.C.S.I.,** Consulting Ophthalmic Surgeon to the Children's Hospital, Birmingham.

**RODWAY, E. A., L.S.A. Lond.,** Medical Officer for the Hamsterley District, Auckland Union.

## Births.

**GALLOWAY.**—August 22, at Epping, the wife of Arthur Wilton Galloway, M.R.C.S., L.R.C.P. Lond., of a son.

**BALL.**—August 23, at 46 Queen Anne Street, London, W., the wife of F. de Havilland Hall, M.D., F.R.C.P., of a son.

**TEEVAN.**—August 24, at St. Kevin's Park, Rathmines, the wife of Deputy Surgeon-General Teevan, J.P., of a son.

## Marriages.

**CASTOR—JOHNSTON.**—August 24, at St. Saviour's, Haverstock Hill, Christian Francis Castor, M.B., to May, second daughter of William Johnston, London.

**COX—HARCK.**—August 25, at Didsbury Parish Church, Richard Percy Cox, M.D., of Iowdon, Cheshire, eldest son of the late W. H. Cox, M.R.C.S., of Manchester, to Louisa Leonides Johanna, eldest daughter of Charles Haugk, Esq., of Didsbury.

**GERMAN—SWAN.**—August 27, at Holy Trinity Church, Hartshill, Frederick Francis German, L.R.C.P., L.R.C.S., of Peasforth, Liverpool, to Evelyn Margaret, younger daughter of the late Thomas Carey Swan, of Eccles, Manchester.

**GILBERT—FIELD.**—August 26, at the Parish Church of St. Stephen's, Hammersmith, Robert Gilbert, M.B., C.M., late of West Ham, Essex, to Eleanor Sarah, eldest daughter of the late Edward Field.

**MANSSELL—MOULLIN—THOMAS.**—August 30, at All Saints' Church, Highgate, Charles Wm. Mansell-Moullin, M.D., F.R.C.S., Fellow of Pembroke College, Oxford, to Edith Ruth, eldest daughter of David Collet Thomas, of Woodlands, Highgate.

## Deaths.

**BURKE.**—August 21, at Loughrea, John Burke, J.P., M.D., B.A., &c., aged 43.

**CHALMERS.**—August 21, David Chalmers, M.D., of Slades, Bramley, Surrey, and formerly of Everton, Liverpool, aged 74.

**DAYMAN.**—August 19, at his residence, Brooklands, Millbrook, Southampton, Henry Dayman, F.R.C.S., aged 76.

**ISEBELL.**—August 27, at 2 Wyebank, Broomy Hill, Hereford, Edwin James Isbell, M.R.C.S., aged 68.

**JONES.**—August 25, at Lichfield House, Weston-super-Mare, William Jones, F.R.C.S.E., aged 73.

**KALI—CH.**—August 23, suddenly, Dr. M. Kalisch, of 35 Longridge Road, South Kensington.

**TEEVAN.**—August 26, at St. Kevin's Park, Rathmines, the wife of Deputy Surgeon-General Teevan, J.P., aged 51.

**WARDLE.**—August 21, at Brighton, John Richard Wardle, M.D., F.R.C.P., of Calverley Park, Tunbridge Wells, aged 65.

### THE TREATMENT OF PLACENTA PRÆVIA.

By J. BRAXTON HICKS, M.D., F.R.C.P. Lond., F.R.S.,

Consulting Physician-Accoucheur to Guy's Hospital; Examiner in Midwifery, Royal College of Physicians, London.

THE treatment of placenta prævia is always a subject that it is well from time to time to discuss, in order to review the various plans suggested for its treatment under the light of increasing experience. It is very gratifying to me to find Dr. James Murphy in his very practical paper on the subject in your issue of Sept. 2nd so fully alluding to the plan I have suggested, and bringing such a list of powerful advocates in its favour; it is also very gratifying to find that the author he so fully quotes—Lomer—is repeating almost word for word the remarks I have made in my little work on "Combined External and Internal Version," 1864, p. 26, on the adaptability of this method to the treatment of placenta prævia. But I am not intending now to discuss the whole question; my chief object in now writing is to note the following remark by Dr. Jas. Murphy:—"As the bipolar method, for some reason or other, has never been taken to kindly in England, the country of its invention. It seems to have been performed by Hamilton in 1822, by Lee in 1843, but was first brought prominently before the profession by Braxton Hicks."

In justice to myself I am anxious to point out that neither Robert Lee nor Dr. Hamilton, nor anyone in England ever employed both the external and internal hands together in either partial or complete version. What Robert Lee did was in cases of arm presentation in premature delivery, work on the foetus by the axilla till the leg presented. What Hamilton says he had done was to bring the head down in arm presentation, but the external hand was not used by either gentlemen as an active agent in turning. The only operator I have heard of, who used both hands—one outside and the other inside, both concerned actively in the manipulation

—was Dr. Wright, of Cincinatti, but only in arm presentations, where he, by raising up the breech of the foetus by the outer hand, thus assisted the inner hand to bring the head to present, or to produce cephalic version. This he did some few years before I published my cases, though I was not aware of it till many years after I published the work above quoted. I may, in passing, remark that the method I suggest is different from Dr. Wright's, using the external hand also to the head. But no one before myself had described the plan of complete podalic version, so that without entering the uterus, save by one or two fingers, we could almost always bring the foot to present instead of the head. Others in Germany had manipulated the uterus by both hands outside before labour to correct supposed mal-presentation, but this is very different from the very practical security, that in the presence of labour, induced or natural, we can rely with almost complete certainty on making the opposite pole of the child to present. There are many reasons why it has not been quite so much used in England as abroad, but it is much more so than Dr. Murphy thinks. The old proverb about a prophet in his own country fairly explains in part; the conservative habit of mind another part. Then in Germany obstetrics are taught, in England learnt. The exhibition of the operations done before a class is much more impressive, than read in the study, or not vigorously enforced in the lecture room. Again, I have not "stumped" the country with repetitions of cases, not because I had no confidence in the usefulness of the plan, but in the assurance that without such aid it would work its way, and thus its proper position would be better assured. But I may mention that my little work was very early translated into German by Professor Gusserow. It was very early employed in Russia, and is extensively used there. I am sorry to find that though Dr. Murphy has used the "combined external and internal version" later in the case, he has not employed it in placenta prævia at the first, for I think he will find it more sure in restraining hæmorrhage than other measures, less disturbing to the patient, and more independent of machinery. Some day he may be called to a case where

the os is small and rigid; the hæmorrhage continuing, or, as in some cases after separating the placenta, urgent; when he may have no Barnes' bags, no professional help, no forceps near. It may be then that he may try, and I feel sure will be pleased with the adoption of the plan I have suggested.

I cannot end without congratulating Dr. Murphy on his successful treatment of these troublesome and dangerous cases; nor without expressing my adhesion to much which he has said in his paper. His excellent results I think are largely owing to his adoption of the resolution to terminate pregnancy as soon as might be possible when it is known to be complicated with placenta prævia; this cannot be too strongly urged, and this I have for the past twenty years, both in class and private, insisted on, namely, that where the fœtus is viable and placenta prævia known to exist, arrangements should be made to induce premature labour, beginning dilatation with Barnes' bags. It may be necessary to induce labour *before* viability; but *after* the risk of fatal bleeding is too great to give away the perfect command of the situation we hold in hand.

## THE NATURE AND TREATMENT OF GOUT.

By Dr. W. EBSTEIN,

Professor of Medicine and Director of the Medical Clinic at the University of Göttingen.

Non fingendum, aut excogitandum, sed invenendum quid Natura faciat aut ferat.—Bacon

(Continued from page 26.)

### CHAPTER IV.—(Continued).

*The Action of Uric Acid and its Compounds, as well as of some Allied Chemical Substances on Animal Tissues and Organs.*

THE following experiments were instituted for this purpose:—The uric acid was in part put into water and shaken up, and partly dissolved by the aid of heat up to the saturation point in a five per cent. solution of phosphate of soda, and, after cooling, filtered. The latter solutions were neutral or very slightly acid. The reaction had no influence on the results. All the experiments were made with sterilised solutions under antiseptic precautions. Injections were now made into rabbits with such fluids, principally with the last-named uric acid phosphate of soda solution, into the peritoneal cavity, the anterior chamber of the eye, parenchymatous injection into the kidneys, the cartilage of the ear, and finally into the cornea. As regards the last-mentioned attempt, it made as little noticeable appearance of irritation as *magnesia usta*, which was made use of in the other eye for a control experiment. Just as little was any morbid condition demonstrable in the peritoneal cavity of a rabbit killed three months after injection of uric acid into it. Uric acid in suspension injected into the anterior chamber of the eye disappeared slowly within two weeks, but without leaving any inflammatory appearances visible to the eye. In the place where the uric acid lay, however, a clouding had remained in the lower part of the cornea. Parenchymatous injections into the cartilage of the ear gave rise to circumscribed hyperæmic spots, which remained for some days and then disappeared, leaving no trace. Parenchymatous injections into the kidney, made in such a way that the fluid injected made its way into the kidney, partly by percutaneous injection and partly by laying bare the kidney, resulted, when the animal was killed forty-five days afterwards, in small-celled infiltration of the kidney, extending far beyond the canal track of the puncture. These experiments were only performed in a few cases, as injection into the parenchyma of the cornea afforded a field for experiment in which the action of uric acid could be easily and unambiguously determined. If some of the uric acid phosphate of soda solution mentioned above be injected

by means of a fine needle into the cornea, a greyish-white cloudiness first arises, which, after some hours, so far clears up that it can only be recognised as a slight clouding by an accurately-focused light. This initial effect is also obtained by injections of sterilised solutions of five-per cent. solution of phosphate of soda. In the meantime, the clouding that thus arises disappears in from one to two hours, and none of those changes takes place afterwards that are constantly observed to take place when uric acid phosphate of soda is injected into the cornea. With the latter the initial cloudiness that arises does not quite disappear. One hour after the injections still no histological changes are recognisable in the tissue of the cornea. If the development of the process is observed later, the slight cloudiness that remains after the retreat of the initial grey-white opacity increases in intensity in the course of the next few days. In the part corresponding to the initial opacity—i.e., in that to which the fluid has penetrated—milk-white cloudings are developed. A breath-like cloudiness of the corneal tissue that appears in the circumference of these, again, disappears in the course of a week, but the milky cloudings remain. If the milky cloudings of the cornea are now examined microscopically, it will be seen that they are infiltrations of it. Such an investigation made two days after the injection of the uric acid phosphate of soda shows with fine sections of the cornea, of which Fig. 25 is a representation with a low power, patchy accumulation of round cells in the substance of the cornea.

Fig. 25.

In the further circumference of these patches, also, disseminated round cells were found, and in large quantities in the tissue of the cornea. Neither crystalline deposits of urates nor necrosed patches were observed in these spots. If the infiltration of the cornea was now followed in its further course, in the spot where this had established itself a change was seen to take place in the course of the next few weeks which had the characteristics of a leucoma in an ophthalmological sense, and which, on microscopical examination, showed accordingly that it was composed of cicatricial tissue.

If a suspension mixture of uric acid was injected into the corneal tissue, the effect was almost exactly similar to that described. Only in one case did there take place about one week afterwards a crater-like loss of substance of a pure white appearance, which later on became covered again with epithelium, whilst a depression remained at the spot implicated. That in this case the effect was not due to the particles of uric acid suspended in the water was shown by the control experiments made with *magnesia usta*. Already after a few hours a considerable clearing showed in the place where the *magnesia* was deposited, and scarcely twenty-four hours afterwards, generally speaking, there was neither any trace of it to be discovered, nor any inflammatory changes to be verified.

These experiments prove that *chemically pure uric acid and its solution in phosphate of soda have an influence on certain tissues in a high degree injurious to their nutrition*, which can be most easily and conveniently followed in the cornea. The course of the keratitic process leaves no room for doubt that it could not have been due to the influence of septic matter; this is also shown without the slightest ambiguity by the simultaneous control injection on the other eye with the same syringe of the solution of phosphate of soda or of the mixture with *magnesia* in

suspension. If I now add to this that parenchymatous injections with two-per cent. solution of urea into the cornea of rabbit were absolutely without irritation, the conclusion does not admit of doubt that *uric acid has an especial irritant action on the tissue of the cornea of rabbits.*

I have now made similar experiments on the cornea of rabbits with a series of other products of metamorphosis, xanthine, guanine, kreatine, and hippuric acid. The two first, as is known, are very closely allied in their chemical constitution to uric acid. But the experiments were all negative. The hippuric acid only caused a cloudiness that remained some days in the neighbourhood of the puncture. This was not present, however, when the acid two-per cent. solution of hippuric acid, which was warmed previous to injection, was first neutralised by soda. All these solutions, after injection into the corneal tissue, cause no other changes than take place after the injection of a five-per cent. solution of phosphate of soda, the effect of which has been described above. The solution of kreatine was neutral, whilst in the case of the kreatinine, xanthine, guanine, the solution made use of was alkaline. Hypoxanthine was, unfortunately, not at my command.

#### CHAPTER V.

##### *Gout of the Human Subject from a Clinical Point of View.*

1. Various divisions of the group of gouty symptoms. Own division into *primary articular* and *primary renal gout*. *Local and general uric acid stasis.* Primary articular gout by far the most frequent form. With this, even when it reaches a high degree, the kidneys may remain sound to the end of life. In any case, the kidneys become affected much later than the joints. Attempt to explain the genesis of articular gout by the formation of uric acid in the muscles and marrow of bones. *The typical attack of primary articular gout.* An aseptic inflammation. Localisation of it; what assists its development. Why the urates only crystallise out in the necrosed parts. Gouty inflammations and changes in organs in consequence of primary articular gout. Significance of the secondary kidney affection for the occurrence of a generalised uric acid stasis. Relations of calculus and of rheumatic and other articular inflammation to gout. *Ætiology of primary articular gout.* The recognised perverse formation of uric acid in the muscles and marrow of bones is in the majority of cases a congenital and lifelong anomaly of tissue change. Predisposing factors. Inheritance of the gouty disposition. Relations of gout to diabetes mellitus. Course, prognosis, diagnosis, and treatment of primary articular gout.

2. Primary renal gout—*i.e.*, those cases of gout in which the kidneys are primarily affected, and in which the other organs are only secondarily affected, and usually to a lesser extent or not at all. Arthritis urtica as a condition consequent on nephritis. Relation of lead disease to primary renal gout. Primary renal gout is much rarer and much more dangerous than primary articular gout. Diagnosis and treatment of primary renal gout.

As I now enter upon the clinical questions affecting gout on the basis of the discussions contained in the foregoing chapters, we shall have the opportunity of proving in how far the views advanced clear up the numerous dark points in the question of gout of the human subject. I hope that these investigations will contribute to illuminate much that is problematical in the complicated symptomatology of gout.

Especially since Musgrave drew attention to the multiplicity of, and the Protean changes in, the forms of gout and established various kinds of anomalous gout, many classifications of the symptoms of gout have been attempted. It would be of no value to discuss them all in this place.

Garrod mentions the newer divisions of Cullen, Mason Good, and Hamilton. He himself, however, not contented with these, made a new classification of the gouty symptoms, which the majority of writers at present follow.

He arranges these under two principal forms—1. Regular Gout; and 2. Irregular Gout.

Regular gout, which may be acute or chronic, consists principally in a specific inflammation in or around one or more joints.

Garrod designates those forms as irregular in which serious disturbances of function or inflammations of tissue are observed which are not associated with the joints. They should, therefore, embrace those forms which have been designated as atonic, anomalously localised, recedent, insidious gout, or as extra-articular gout, &c. Whilst on the basis of my observations, I do not accept the dictum of Garrod that gouty inflammation is always accompanied by deposition of urate of soda in the inflamed parts, I accept Garrod's conception of irregular gout. The deposition of crystalline urates only takes place after the uric acid has destroyed the tissues; if it injures them to a lesser extent, if, for example, it only sets up inflammation of them, then the uric acid combinations, for reasons to be discussed later on, do not crystallise out in the tissues and organs. But these processes are also gouty, *i.e.*, they are caused by uric acid. Both are perfectly regular processes in the course of gout. They find their explanation in the above-explained mode of action of the gouty poison—*uric acid.*

Garrod's classification into regular and irregular gout acts far more confusingly than explainingly for the understanding of the subject; neither has it any significance practically after it has once become clear that the various organs may be damaged in varying extent and intensity by uric acid. On the contrary, I believe that we shall most easily understand the clinical history of gout, its ætiological and pathological relations, the varying course, the things relating to the grouping and sequence of symptoms, and the termination of the disease when we accept *two principal types* in gout—*viz.*, 1. *Primary articular gout*, and 2. *Primary renal gout*. It is common to both that they may be complicated with gouty diseases of various other organs. The first is by far the most frequent form. It affects by preference, but not exclusively, the well-to-do classes of the population. The second form, primary renal gout, is much less frequent. It threatens life much earlier than the first by the disturbances of the renal functions, which are present from the outset, and by the unavoidable conditions consequent upon these. Here belongs that first gouty symptom in serious kidney disease, especially in inflammations of the kidneys—*nephritis urtica*. The first category of patients, those who suffer from primary articular gout may die without the kidneys being found diseased, the second category often succumb to the gouty process, without the cartilage or any other organ than the kidney being affected.

This classification of gouty diseases has never been distinctly drawn, although, after what Dr. W. H. Dickinson has sketched out in short sharp lines on the basis of his own observation, it lies open to the view. In respect to this Dickinson speaks as follows:—

"The gouty affection of the kidneys may run its course without any other signs of gout.

"The gouty affections of the joints and those of the kidneys are associated as both arising from a common cause.

"When the disease attacks the joints we have the usual symptoms of gout; when the kidneys, the characteristic granular degeneration.

"It appears that in those cases in which the gouty affection is caused by alcoholic drink it attacks the joints by preference, but in those in which it can be traced to lead poisoning, it specially attacks the kidneys.

"The rich man rejoices in a long life with the gout in his extremities; the handicraftsman succumbs to the like disease of the kidneys before his joints are affected."

## THE LATEST TEACHINGS OF THE HOPITAL DU MIDI, PARIS.

*Being the Presidential Address at the Opening of the  
Second Session of the Willan Society of London  
in 1885.*

By C. R. DRYSDALE, M.D.,

Senior Physician to the Metropolitan Free Hospital, and to the Rescuer  
Society; President of the Willan Society.

GENTLEMEN,—For many centuries the diseases of the skin were ill-studied and misunderstood, physicians thought them beneath their notice, and abandoned their treatment to empirics. At the end of last century Plenck, of Vienna, and Willan, of London, commenced to throw some light upon this dark region of pathology. Willan and his pupil Bateman regularly defined the lesions observed in skin diseases, and gave a precision to the nomenclature of these affections. In France, Bielt, followed by Gibert, Cazenave, and Devergie, took up this subject, so that by their labours a skin disease was named as easily as a plant by a botanist.

When we study these diseases we begin to find out that the form is only a secondary consideration, and recognise that the same disease may at one time be vesicular, at another pustular, at another squamous. For instance, in scabies and eczema we may see simultaneously both vesicles, pustules, and squamæ. The nature of the disease has, therefore, become of late the more important point in classification; and now that we possess a knowledge of the graphic characters of skin affections, our business is to elucidate the question as to their nature, and to endeavour to discover to what natural group each belongs, just as in the human race we are not certain of the personality of any one individual unless we know what is his surname. Eruptions have also a family name which gives us an idea as to their cause, progress, relapses, and treatment. In scrofulous affections of the skin, for instance, and in syphilitic skin diseases, the eruptive form evidently holds the second place in the disease, whilst the question of their nature ought to be placed in the foremost rank. Willan divided the elementary lesions of skin disease into eight groups. Maculæ, exanthems, vesicles, bullæ, pustules, papules, squamæ, and tubercles. Since his time Hardy has added three others, viz., blood stains (purpura), sebaceous alterations, and parasitic productions. Turner, in 1774, classed cutaneous diseases into those of the hairy scalp (tinea), and those of the skin (dartrous). In the classification of Willan and Bateman, measles, varicella, and variola, diseases so analogous that no one nowadays hesitates to group them as one class, figured—(1) among the exanthems, (2) among the vesicles, and (3) among the pustules, thus placing small-pox in the same category with impetigo and ecthyma. No therapeutic practice could be based on such a classification as this; and it was, therefore, gradually abandoned. In 1776 Plenck, a Vienna physician, divided diseases of the skin into fourteen groups, but he made some groups which were useless, such as crusts and ulcerations, which were only the products of inflammation at a certain point. The next division was that of Lorry, in France, who divided skin diseases into those which arose from an internal, and those from an external, cause. Alibert, of the Hôpital St. Louis, of Paris, an eloquent professor, was a great opponent of Willan's classification. He proposed another, and sought to do what Jussieu undertook for botany, i.e., he tried to establish a natural dermatological classification. He was, however, unlucky in the choice of his names, and hence his system was not carried out.

During this century we have had quite a host of celebrated names in this department of medicine, Erasmus Wilson, Hutchinson, Startin, Tilbury Fox, Milton, Squire, and many others yet living in this country and in Scotland, and Hebra and Kaposi, in Vienna, and other able names which I have not space to mention.

Gradually a true and scientific knowledge of this part of medicine is being laid down, although there is quite enough left, we may be sure, to stimulate to further exertion, and I trust that the Willan Society may prove one of the most useful fields for the study of these very common and disagreeable affections.

Classification of skin diseases are all rather imperfect, but the one proposed by Dr. Hardy, of Paris, has always seemed to me very useful in practice.

The first class of skin diseases embraces deformities and maculæ, the affections named ephelis, vitiligo, and lentigo. Warts, molluscum, ichthyosis, and keloid are to be found in this class. Local and surgical treatment alone are of service.

The second class, that of local inflammations, comprehends erythema, urticaria, herpes, ecthyma, and pemphigus. Local and general antiphlogistic remedies are indicated here.

Parasitic diseases of the skin, the third class, contains itch, sycosis, herpes circinatus, and favus. The destruction of the parasite is here of prime importance.

The fourth class embraces the eruptive fevers such as scarlatina, measles, and variola, and I think syphilis may be placed in it. Vaccination is the preventive of variola, expectation the present treatment of scarlatina and measles, and specific treatment is necessary in syphilis.

The fifth class, that of symptomatic eruptions, comprehends the rose spots of typhoid, sudamina, purpura, and herpes labialis.

The sixth class is that of constitutional eruptions, including eczema, psoriasis, lichen, and pityriasis. These require constitutional treatment and also local applications.

The seventh class is that of scrofula, and this requires constitutional treatment.

The eighth class, cancer, is treated by excision.

Finally, there is a ninth class, which refers to the exotic diseases, such as tubercular leprosy, the treatment of which is not well understood in this country, as cases of them are so rarely met with.

I place syphilis among the exanthems, because it has now been discovered that that disease, just like the fevers, has a lengthened period of incubation, occasionally a time of high pyrexia, and after this a long period of eruptions, during which it is communicable. All this points to the view that syphilis, like the exanthems, is a germ-produced disease, and although it is not like variola or measles in the rapidity of their evolution, it resembles these diseases in the extreme rarity of second attacks of the disease. This shows that it is a zymotic or fermentative disease like them. I will take syphilis for the subject of my remarks this evening.

The Hôpital du Midi of Paris has long been noted for the careful attention paid by its staff to the complicated diseases classed as venereal. Those who are familiar with the literature of syphilis before the era of Ricord, Bassereau, Rollet, and Fournier, the latter gentlemen being pupils of M. Ricord, cannot fail to acknowledge that the gratitude of mankind is due to those most accurate observers for making that which was once shrouded in mystery plain and comprehensible to all.

Of all viruses, syphilis is one of the most interesting and instructive, since it is so varied in the symptoms it gives rise to, and so comparatively amenable to treatment. In passing, too, I may call to mind that it was in this disease that the idea of curing a malady by the inoculation of mitigated virus was largely experimented upon some years ago by my friends the late Dr. Boeck, of Christiania, and Dr. Auzias Turenne, of Paris, who in this matter were the forerunners of Pasteur and that modern school which promises us the cure of disease as well as its hygienic prevention by means of the introduction of such cultivated viruses into the system.

Having visited Paris in July last, I was anxious to compare the theories of London, as held by Mr. Hutchinson and other most distinguished writers, whose opinions are here held in such esteem, with those of the present

École du Midi, and to this purpose I paid a visit to my good friend M. Charles Mauriac, who is the worthy successor of M. Ricord as lecturer at that hospital. That gentleman gave me most categorical replies to my queries, and, at the same time, favoured me by handing me his work published last year, of 1,072 pages, entitled "Lectures on the Venereal Diseases delivered at the Hôpital du Midi," so that I was in a position to control the oral communications I had from M. Mauriac by an appeal to his written opinions.

In London at this moment there is a good deal of confusion concerning the division of these diseases. Mr. Jonathan Hutchinson, for instance, says that so-called *Dualism*, or the doctrine that there are two viruses of distinct nature, one of which produces the chancre of syphilis and the other the soft chancre, is dead. He asserts that the soft sore is a product of syphilis, and that it bears the same relation to syphilis as the abortive vaccine vesicle does to the true or successful vesicle. Mr. Cooper, too, in a most admirable work on syphilis, published this year, disclaims all belief in dualism, and holds that the soft chancre is no peculiar sore, but that it is possible to create such a sore afresh by means of some kinds of pus, such as that of ethyma or of acne. He bases this opinion upon certain experiments; and we may also remember that a late distinguished surgeon, Dr. Morgan, of Dublin, related in the Medical Society of London some years ago how that he had succeeded in producing soft sores upon syphilitic women by inoculating them with the secretions from their vaginas.

M. Mauriac is—and I share his views on this point—very sceptical as to the power we possess of producing afresh a sore so well-marked in its properties as the soft chancre is. He is indeed a pronounced dualist, and believes that the virus which produces the syphilitic sore never produces the soft sore, and again that the virus of the soft sore only produces that ulceration. There are three viruses—the gonorrhoeal, the soft chancre virus, and syphilis. The first of these three has always existed, is capable of being produced by ordinary irritation of the urethra, and will last as long as the human race lasts. On the other hand, the virus of soft sore is always derived from some person who has an ulcer of the same kind, and thus this form of venereal disease, as also true syphilis might be stamped out by hygienic care, and doubtless will in the long run disappear.

However well ascertained, says Mauriac, these facts are at the present day, to all non-prejudiced minds, many efforts have been required to make them triumphant. The confusion which commenced in the description of the venereal diseases in 1520 was universal in 1850. First of all the soft chancre was added to syphilis, and the chancreous bubo. Then came the turn of gonorrhoea, which Brasseavola made a symptom of syphilis. Until the year 1700 confusion reigned supreme. Benjamin Bell, Hernandez, and Ricord removed gonorrhoea from the category of syphilitic symptoms, but the virus of simple chancre and syphilitic sore remained confounded until the middle of our century.

Thirty-four years ago men still believed, and M. Ricord professed, that the two chancres are due to the same virulent principle, and that, if their consequences are in the one case local and in the other constitutional, this capital pathological circumstance only depends on conditions foreign to the virus itself and inherent in the soil in which it is implanted. After long struggles, which re-echoed afar off, and the memory of which is not effaced even now, a new doctrine, that of *dualism*, carried the day in Paris. It was to a French physician, Dr. Basereau, that the honour is due of having enforced this truth on the minds of all unprejudiced persons. In 1852 he assembled his proofs ascertained at the Hôpital du Midi. This is the real year from which all modern doctrines with regard to syphilis should be dated. Such are Mauriac's views: they are also mine. There is no doubt that gonorrhoea has always existed in the history of the

race; and soft sore has existed according to Mauriac in antiquity among the Greeks and Romans.

*Origin of Syphilis.*—Many writers of ability maintain that syphilis was common among the Greeks and Romans; but among the ancients one is struck with the absence of all documents on the subject. It has always seemed to me to be a kind of injustice to the physicians of antiquity to suppose that they should have been so blind as not to recognise a disease so evident as syphilis often is. Can we suppose that they were less observant than the practitioners of the Middle Ages? What happened when syphilis broke out at the end of the fifteenth century? It was not confounded with any other disease. Common sense, then, would make us believe that syphilis had a modern origin in Europe at least. As to the query whether the disease came to us from America or was spontaneously generated in Europe by a kind of Darwinian origin of species, this is still a very obscure point. But after examining all the evidence, the American origin of the disease and its first appearance in Europe in modern times seem to unite the greatest amount of probability in their favour. Authors who are persuaded as to the American origin say that it was on May 13, 1493, that the sailors under Columbus, on their return from the West Indies to Barcelona, imported the disease with them, a year before the appearance of the malady in Italy. Objectors point to an edict of Paris in March 25, 1793, which leaves no doubt as to the existence of syphilis in that city, and Battista Fulgoso, who was Doge in Genoa from 1478 to 1493, mentions that there was a new disease then which none of the physicians had seen before, and which they named *mal napolitain* in France, and *mal français* in Italy. Some years ago, too, a French writer, Captain Dabry, wrote a work on "Medicine among the Chinese," and alleged that the disease had been completely studied and described as far back as 2,637 years before Christ. Critical works have not failed to point out numerous unfounded assertions in this work of Dabry's, and the story has, I believe, been discredited.

Whether syphilis came, then, into Europe from America, or by more hidden routes from the East, or from Africa, it found everywhere in the Old World a virgin soil of remarkable fecundity, which communicated to it a vigour it had never before attained to, or since exhibited, although it is still extremely prevalent. Speaking historically, at any rate, we may say that the description of syphilis dates from the end of the fifteenth century.

Professor Joseph Jones has lately written a learned article upon syphilis among the aborigines of America. Bones dug up from the tombs of Georgia, Tennessee, and Kentucky present, according to that author, lesions which were indubitably caused by syphilis. There were symmetrical thickenings of the tibiae, of the cranial bones, and of the sternum, clavicle, and radius. "The diseased bones which I have collected (said Dr. Jones) in the stone tombs of Tennessee and Kentucky, are probably the most ancient existing on the globe. This discovery (he adds) appears to me to have a great importance in the history of specific and contagious diseases; it corroborates this opinion sustained by some pathologists that syphilis has originated in western countries."

The *virus of gonorrhoea* is not distinguishable by the microscope; but it probably resides in the solid parts of the pus, since the violence of the disease and its contagion are proportionate to the number of the pus globules. In the midst of these elements, there have, from time to time, been shown the existence of animal and vegetable parasites, such as the vibrio lineola, and the trichomonas; but said parasites do not by any means constantly exist in the fluids of gonorrhoea. Gonorrhoeal pus when inoculated produces scarcely any effect, unless it is inoculated on a mucous surface such as the urethra or the eyes, when, after an incubation of two or seven days, a purulent catarrh supervenes.

The *virus of soft chancre* is constituted by pus and sometimes by blood, and the organic *débris* which result from the melting down or gangrene of the tissues. It is

remarkable for its contagiousness, and for the extreme facility with which it is reproduced. The contagious principle in this case, as in gonorrhoea, probably adheres to the pus globules, and is constituted by them. M. Chauveau demonstrated this fact recently in the case of variola, vaccinia, and malignant pustule. M. Mauriac some years ago collected a sufficient quantity of virulent pus from soft chancres or virulent bubos, and separated it into two parts by filtration, the one serous, the other solid. He always had negative results when he inoculated the serous portion; but this also took place when the solid portion was used, so that the experiments were not of much use.

When such inoculations succeed what occurs? There is first of all a very short incubation, or rather no incubation, and there appears a small inflammatory papule. On the third day there forms at the top of the papule an elevation of the epidermis by a liquid, which is at first serous, than whitish, and then purulent. This becomes a pustule which is not slow to burst. This chancre is inoculable and re-inoculable every where on the same patient indefinitely. If the pus of simple chancres were to disappear for some years, it could not be created again like that of gonorrhoea; but Mauriac hazards the opinion that it would ere long be born again by the action of the unknown causes which have presided over its first formation. It is always circumscribed, and localised in a region or in an organ, and has no effect at all on the general organism.

The professor of the Midi at present teaches, as Ricord taught, that the virus of syphilis is not inoculable on the person who has syphilis. After the virus has been introduced under the skin, at the end of a variable time, twenty-five days on an average, and often much longer than that, a papule is seen at first dry, leaving in a short time an erosion by the falling of the epithelium. Shortly after this the base becomes indurated and the glands nearest begin to enlarge. Bidenkap and Morgan did not, says Lee, produce a soft sore, but another or inflammatory sore by these inoculations.

(To be concluded in our next.)

## HISTORY OF THE PROGRESS OF LARYNGOLOGY FROM THE EARLIEST TIMES TO THE PRESENT.

By GORDON HOLMES, M.D.,

Physician to the Municipal Throat and Ear Infirmary, London; Consulting Physician to the Sheffield Ear and Throat Hospital.

Il importe beaucoup de connaître l'histoire de la science à laquelle on s'attache.—Boerhaave.

### EPOCH II.—THE LARYNGOSCOPIC AGE.

(Concluded from page 200.)

*Anatomy.*—Anatomical researches, it must be allowed at once, owe little or nothing directly to the laryngoscope, although the educational study of the anatomy of the larynx has unquestionably become more general and been pursued with more attention owing to the extension in practice of laryngology.

Some facts of more or less importance in the minute anatomy of the larynx have been brought to light within the last quarter of a century. In 1859 Hubert von Luschka, (3) professor of anatomy at Tübingen, discovered a pair of small cartilages, about the size of a pin's head, in the tissues external to and below the apices of the arytenoid cartilages. He named them the "posterior sesamoid cartilages;" they are inconstant, occurring only in about 40 per cent. of cases. In 1873 he noted also that an "interarytenoid cartilage," a small fragment suspended almost centrally in the space between the arytenoid cartilages posteriorly, is exceptionally present in man. Such a cartilage is found, well developed, in the *gulo borealis* (glutton). Luschka published in 1873 the finest and most exhaustive work (4) hitherto seen on the anatomy of the human larynx.

It is illustrated by ten lithographic plates executed to perfection, depicting in sixty-nine figures the relations and parts of the organ, including microscopic sections, &c.

In 1874 P. Coyne, (5) in his graduation thesis at Paris, set forth some valuable researches on the normal anatomy of the mucous membrane of the larynx. The points revealed by this observer are:—1. The bed adjacent to the epithelium consists of a reticulated lymphoid tissue, like that found in similar relationship in the small intestine. 2. Closed follicles, similar to those of the small intestine, exist in the superficial part of the mucous derma, estimated at 30 to 40 in number. 3. On the free edge of the vocal band papillæ are found, "certainly vascular and probably nervous;" (6) they are best developed anteriorly.

*Physiology.*—Garcia's (7) observations with the laryngoscope at once made it objectively certain that all laryngeal tones, grave and acute, emanated solely from the vibrations of the vocal bands, and that the ventricular folds (false cords) had no obvious part in sonorous voice production. Czermak (8) further noticed that during the hermetic closure of the larynx which takes place in holding the breath for various efforts, &c., the ventricular folds were closely approximated, the outlet of the larynx being simultaneously much narrowed by the near approach of the arytenoid cartilages and the epiglottis. He also investigated with the laryngoscope the formation of the laryngeal consonants (*gutturales veræ*) from the faintest aspirates (*spiritus asper*, or "rough breathing," of the Greeks) to the intense *ââ* of the Arabs, &c. He observed that the production of these letters depended on various degrees of the same action as that required for hermetic closure, thus demonstrating the actual vocal functions of the ventricular folds. He thus afforded practical confirmation of the theories put forward in 1856 by the philologist, E. W. Brücke, (9) of Vienna.

In 1866 J. Wyllie (10), of Edinburgh, made some experiments on the detached larynx, with the object of ascertaining, amongst other questions, the mechanism of hermetic closure. He concluded that the chief factor in this action is a valvular disposition of the ventricular folds brought about by lateral pressure of the air which from below passes into and distends the ventricles. This experimental result appears to agree exactly with the theory of Galen.

*Pathology.*—To provide an easy method of studying visually conditions of an organ which previously could only be seen in the post-mortem room, must effect a revolution in the clinical practice of any department of medicine. The conception of such an occurrence is fully exemplified by the laryngoscope: in its invention the before almost impracticable science of laryngology at once became a busy and cosmopolitan specialty; whilst even the routine practitioner felt it a duty to make an accurate diagnosis in cases where vague, perhaps entirely wrong, inferences had before seemed all that could be fairly required from the physician.

The subject of laryngeal phthisis (a name which since the essay of Trousseau and Belloc had gradually been restricted to tubercular manifestations in the organ) has been studied diligently with the laryngoscope, and the objective phenomena of its progress, from the earliest to the final stages, have been noted with great accuracy by many observers. Notwithstanding the lucid description of Rokitansky, some incredulity prevailed for long afterwards as to the existence of laryngeal tubercle, but this has been gradually dispelled by the researches of Virchow, Förster, and others, but especially by those of Heinze, of Leipzig, who in 1873 published an extensive monograph on the disease. Heinze's work (11) is mainly founded on the microscopical examination of forty-seven cases (autopsies), in thirty-eight of which he found tubercle in every stage of development and decay. The book is fully illustrated by chromo-lithographs of the microscopic views. The obvious conclusion respecting laryngeal tubercle is that in consumptive patients the clinical features of phthisis of the larynx are in most cases, if not in all, accompanied by an actual deposit in the organ of the morbid product. (12)

The discovery of the tubercle bacillus in 1882 by Koch, of Berlin, has, of course, an important bearing on every form of phthisis and Fränkel (13), of the same city, has shown how, in doubtful ulcerations of the larynx, a diagnosis may be arrived at by removing with a brush some of the discharge from the surface of ulcers, and examining microscopically for the bacillus.

No more signal evidence of the value of laryngoscopy

could be adduced than that afforded by the history of growths in the larynx. Some centuries of pathological investigations under ordinary conditions brought to light scarcely forty cases, but under laryngoscopic inspection in less than two decades nearly a thousand instances have been published, whilst a far greater number have probably been observed and treated of which there is no printed record. The first case of a laryngeal polyp is appropriately due to Czermak (14); by 1871 the number published had reached to 189, and in that year Mackenzie (15) issued the details of 100 cases of his own, accompanied by full lucubrations based on these and all previous cases. But even this remarkable achievement was to be outdone, for, five years later Fauvel (16), of Paris, presented in print the history of 300 instances treated by himself. Thus, it may be seen that for many years the laryngoscopist treasured up all cases of laryngeal polyps, like gems which it was necessary to preserve and exhibit in suitable settings, but latterly the rather monotonous recapitulations of nearly similar instances have been almost crowded out of medical literature.

The general conclusions arrived at respecting benign growths in the larynx are that (a) they constitute about one per cent. of cases of laryngeal disease; (b) they are most frequent between 30 and 40 years of age; (c) three-fourths of them are situated on the free edge of the vocal bands; (d) as to histological nature, papillary growth greatly predominates (nearly 75 per cent.), and most of the remaining cases consist of mucous polypus like those of the nose (myxomata), or of fibrous tumours (fibromata), whilst a small number of glandular and vascular formations (adenomata and angiomata) complete the pathological series.

The curious occurrence of a tumour formed by eversion or prolapse of the ventricles has been observed first by Moxon, (17) in 1868, at an autopsy. The third case published was diagnosed by Leferts, (18) of New York, with the laryngoscope in 1876, and here both ventricles were everted.

Cancer of the larynx has been also extensively observed with the laryngoscopic mirror. The best account is that of Fauvel (19) who furnishes a minute description of 37 cases primitive in the organ. Of these 19 were encephaloid, 16 epithelioma, 2 doubtful, 16 certainly, and 10 probably began in the left ventricular fold. Secondary cases in which the larynx becomes involved by extension from the neighbouring parts have also been frequently met with. Here the observations of Butlin (19) on the modifications of cancerous structure, proper to various organs, which he has extended to the larynx, must not be overlooked.

Syphilis has also been well studied in the larynx, and besides the usual ulcerative phenomena the laryngoscopist has made practitioners clinically acquainted with the often consequent cicatrices which produce stenosis of the glottis by rendering the vocal bands adherent, or contract the channel of the windpipe in other situations; also with condylomata and gummata as very unfrequent manifestations in this part. The first descriptions of laryngeal condylomata are due to Gerhardt and Roth (20) in 1861, of gummata to Türk (21) in 1866.

On no division of laryngology has the laryngoscope thrown so much light as on that of laryngeal paralysis. In 1861 L. Mandl, of Paris, called attention to the fact that hoarseness and aphonia were markedly more common in pulmonary phthisis when the apex of the right lung is consolidated. He attributed this circumstance to pressure on the right recurrent nerve on account of its being contiguous to the pleura, but he erred in setting down many cases due to structural alterations as proceeding from this cause. In 1863 Gerhardt, (23) of Jena, published an elaborate article on eighteen instances of laryngeal paralysis observed laryngoscopically by himself, in which he advances the science of the subject almost to the furthest point yet attained. Entering on his theme with a conception of its fullest extent he remarks:—"The needful task in this inquiry is to recognise more fully the results of paralysis of each laryngeal muscle, of each pair of muscles, and of whole groups of muscles, both as to voice and respiration; further, to explain the consequences of paralysis of one or both recurrents, of one or both superior laryngeal nerves, and lastly of paralysis arising in the fibres proper of the vagus or of the spinal accessory." In accordance with this definition Gerhardt proceeds to describe in detail the various phenomena referred to, but the clinical and experimental evidence was, as it still remains, too impure to admit of this work being

executed in all its parts with precision. Finally, he recounts his cases, which exemplify hysterical or functional aphonia, myopathic paralysis of a rheumatic nature, and nervous disease of cranial origin or arising near the lungs from pressure of tubercle. Amongst them occurs the first instance practically observed of paralysis of the posterior crico-arytenoid muscles (laryngo-plegia of Albers). The symptoms of this affection are given with exactitude by Gerhardt:—"Should the posterior crico-arytenoid muscles on both sides be alone affected, then does the strong contraction of the antagonists produce a glottis-narrowing continually progressive, with each inspiration, almost to closure. The inspiration breath-stream urges the vocal bands so near together that against the edges of the extremely narrow glottis-chink which remains a loud friction sound arises (audible inspiration), the voice is unaltered, whilst in recurrent paralysis it is essentially changed." All examples of this paralysis, like those of growths, were for many years published most scrupulously, but, owing to their scarcity and sameness, the record has not attained forty cases. They appear to occur not oftener than twice per thousand among laryngeal patients (24). In this connection Semon's (26) researches, especially as to the proneness of the fibres of the vagus ruling the respiratory motions of the larynx to succumb first in organic disease of that nerve, are of great value.

In 1867 Mackenzie applied to the larynx the mode of classifying paralyzes according to their interference with adduction, tension, &c. This division is of more clinical significance than an anatomical one, as it facilitates the recognition of the various affections by fixing the mind of the observer on the laryngoscopic semeiology of each. Having recently emended and extended his system, he now reckons (1) unilateral and bilateral paralysis of the lateral adductors (lateral crico-arytenoids), of the abductors (posterior crico-arytenoids), of the internal tensors (thyro-arytenoids), (2) and of the external tensors (crico-thyroids); and lastly, paralysis of the central adductor (arytenoid muscle).

In 1877 Von Ziemssen, of Munich, published a very complete account (3) of diseases of the larynx, including the neuroses. In the latter department his observations have much enlightened us as to lesions of the superior laryngeal nerve, which produce anaesthesia of the mucous membrane, with relaxation of the epiglottis and vocal bands. He is also the first to describe isolated paralysis of the arytenoid muscle, evidenced by inability to close the cartilaginous glottis, and to represent correctly the laryngoscopic appearance following paralysis of the thyro-arytenoids, viz., an elliptic gaping of the vocal bands during phonation.

The pathology of croup or laryngeal diphtheria, as most practitioners now acquiesce in naming it, has only been advanced in the laryngoscopic period by a better microscopical study of the false membrane. The impressive discovery in connection with this production is that, although it has many of the physical and chemical qualities of fibrin, it has in reality no affinity with that substance. This point was brought out by Rindfleisch in 1866. "If small pieces," says he, (4) "are soaked in a weak ammoniacal solution of carmine, then washed and teased out with needles, we can easily convince ourselves that they consist of cells and nothing but cells, which on account of a peculiar degeneration of their protoplasm and an equally peculiar junction with one another cause a macroscopic appearance of coagulated fibrin. But for the carmine-red spots indicating the nuclei we might fairly err as to the cell-nature of their irregular, angular, glistening, and agglutinated flakes." The false membrane, as Rindfleisch remarks, occupies the position of the normal epithelium, and the researches of E. Wagner in 1866 (5) go to prove that it actually originates in a peculiar action of the epithelium accompanied by a metamorphosis of its elements.

The remarkable form of chronic laryngitis, seemingly connected with scrofula, in which there is hypertrophy of the mucous membrane of the oblique under-surface of the vocal bands, often demanding tracheotomy, was first observed laryngoscopically by Czermak, (6) and many other practitioners have since reported cases. Whether, however, it is an affection *per se* or merely differs from ordinary chronic laryngitis by its site is yet undecided.

In 1874 Coyne (7) investigated the state of the larynx in scarlet fever more minutely than any previous observer. He found lesions varying from ordinary catarrh to severe ulceration from necrosis of the mucous membrane, and even a diphtheritic inflammation of the organ. He confirms the

pathological conclusions of Wagner as to the production of the false membrane, and hence proposes the name of "epithelial laryngitis."

Those rare affections of the larynx, some of them common enough, however, in certain districts, lupus, lepra, elephantiasis, glanders, erysipelas, have been frequently described from laryngoscopic inspection. Virchow (8) is the chief investigator of their pathology.

*Treatment.*—The local treatment of diseases of the larynx dates practically from the introduction of the laryngoscope, for, notwithstanding the ingenuity of Trousseau and Belloc and Green, the pre-laryngoscopic difficulties of diagnosis caused their devices to be esteemed as uncertain—almost absurd, by practitioners in general who had not cultivated a special expertness in this department.

In this section we have to notice the development attained in treating the larynx topically by application of solutions, inhalations, insufflations, and galvanism, and by intra-laryngeal and extra-laryngeal operations.

To see the larynx inflamed or ulcerated was to resort to local applications for the relief of such conditions, and thus the use of drugs in solution, or even solid, to be applied with brushes, sponges, &c., mounted on suitably curved handles, was almost simultaneous with diagnostic laryngoscopy. Hence local medication of the larynx almost immediately attained the same magnitude as in the pre-existent treatment of external parts; in other words, the larynx virtually became to the practitioner as an external organ, and in disease was treated as such.

The therapeutic inhalation of steam or fumes rising from liquids, &c., impregnated with various drugs is, as we have seen, of prehistoric date, but the immense extension in the use of remedies in this form is due to laryngoscopy.

About 1868 Mackenzie published a pharmacopœia of throat remedies in which this kind of inhalation held a prominent place, and an array of formulæ was first presented with a scientific method. The principle of medicating the steam adopted was the addition of various essential oils, previously suspended in water by trituration with light carbonate of magnesia, to the hot water. From considerable experience, however, I am inclined to doubt as a rule the therapeutic activity, beyond the effect of the steam, of such inhalations. As a substitute for the essential oils in this form I can strongly advise that an extensive trisal should be given to tinctures, particularly such as are miscible with water, likely to have a beneficial local action in each case.

The employment of spray or atomised fluids for inhalation is, however, scarcely older than twenty-five years. About 1850 attention was first paid to the fact that in steam inhalation little or none of the medicament in solution is in many cases given off in a volatile form so as to be carried into the air passages. The idea of inspiring the liquid bodily in an atomised state then arose, and in 1855 Sales Giron (9) invented the first efficient spray inhaler. This instrument was simply a small force-pump, which, by causing a fine stream of the liquid to impinge against a resisting surface, dashes it to atoms. Modifications of it have frequently been made, and are still in use. No sooner had the system of spray-inhalation been practically adopted than doubts were entertained of its efficacy, it being said that almost all the particles were arrested and condensed in the mouth and pharynx. Various experiments were then undertaken in order to prove the penetration of the medicaments into the windpipe and bronchi. Of these the most conclusive was that of Demarquay, (10) who, about 1861, in a patient on whom tracheotomy had been performed, demonstrated the presence of tannic acid in the trachea after a spray solution of that substance had been inhaled. In 1864, Bergson of Berlin, introduced a spray inhaler on the principle of causing a vacuum in a vertical tube dipping into the solution by blowing across the top of it through a horizontal tube, (11) the method used in the well-known ether spray apparatus, &c. In this device the spray is too cold to be always of appropriate applicability, and to obviate this objection Siegle, (12) of Stuttgart, in 1865, invented the modification of it, in which steam plays the part of the current of air, thus gaining also the advantage of its being self-acting. In 1863 Lewin, (13) of Berlin, published a work containing an enormous amount of literary and practical information as to inhalation, especially in relation to laryngeal disease.

Medication of the larynx by insufflation of powders has

also been extensively practised. The powder is placed in a tube curved at one end, so that it may be passed down close to the larynx, and a current of air is furnished from the mouth or by compression of an india-rubber ball joined to the outer edge of the tube, the invention of Raachfuss, of St. Petersburg.

The ancient hypoglottides have also come prominently to the front, in the form of numerous kinds of throat lozenges, but this kind of local medication has the great disadvantage that the stomach and intestines must subsequently receive the drug, often in large quantities, and may be injuriously affected thereby. So gravely has this objection been felt by some practitioners that it is understood that in America throat lozenges have already been almost abandoned in favour of a more extended use of spray solution.

Galvanism in laryngeal paralysis was first extensively resorted to by Gerhardt. (14) According to this authority Grapengiesser, of Berlin, in 1800, first tried to cure a case of aphonia in a girl, *æt.* 17, by electricity. Subsequently Sedillot, Althaus, and others used the remedy occasionally. At first the continuous current was employed, but after the discoveries of Faraday, about 1835, relating to induction, the interrupted current was preferred as the most effective. Gerhardt and his predecessors, however, only applied the galvanism to the neck, and the larynx was only fully subjected to the influence of this remedy in 1863, when Mackenzie invented the well-known laryngeal electrode, intended for bringing one pole in direct contact with the mucous membrane of the organ, whilst the other acted through the skin externally. This instrument was soon modified by Fauvel and Ziemssen, who constructed it with a bifid extremity, so that both poles could be applied to the larynx internally, and the current directed in the course of the muscles with exactitude.

With respect to tracheotomy we have to record its adoption as a means of cure in severe chronic diseases of the larynx, when, by relieving the organ of its functions, a state of quiescence most favourable to every reparative process may be obtained. This extension of the operation was made by Bryant, (15) of London, in 1868, and appears to be gaining considerably in the confidence of the practitioner on the Continent and in America. The improvements in tracheotomy instruments are the substitution of right angled for quadrant cannulae by Durham, in 1868; the invention of the "lobster-tail" trochar or pilot for guiding the tube firmly into the trachea, especially at the first insertion; the devising of the india-rubber cannulae by Marrant Baker; and lastly, the construction of the tampon cannula by Trendelenburg. The latter instrument is intended for operations in or about the larynx when there is danger of suffocation from blood passing down the windpipe. A narrow belt of caoutchouc surrounds the internal end of the cannula, after the introduction of which it can be inflated from the outside by means of a small communicating pipe, thus completely blocking the trachea.

Extirpation of the larynx in cases of carcinoma or other incurable disease localised in the part was first undertaken by P. H. Watson, (17) of Edinburgh, in 1866, and again by Billroth, (16) of Vienna, in 1873. Since then about sixty-five further instances have been published, but it is still doubtful whether the operation has ever prolonged life. (18) An artificial vocal apparatus (often since modified) was devised by Gussenbauer for Billroth's case, which enables the patient to speak intelligibly in a monotone.

Intra-laryngeal operations have attained the greatest possible magnitude, and, by the aid of the laryngoscope, scarification, dilatation, and division of strictures and excision of growths and foreign bodies have been practised in almost innumerable cases by most of the authors named in this period, and by a still greater number of laryngologists who have not published their proceedings. In this way hundreds, or, to speak more truly, thousands of persons have been relieved of some obstacle in the windpipe with little or no suffering, who would formerly have had to encounter the severity and danger of tracheotomy. To meet the requirements of intra-laryngeal surgery the various operators have invented in large numbers suitable forceps, snares or écraseurs, guillotines on the principle of the tonsillotomy, dilators, lancets, &c., all of such size and form as to enter the larynx with facility. Of these no further notice is here needed, but we may refer to the special ingenuity

in this field of the Vienna practitioners, Schrötter, Störk, and Schnitzler. The application of the galvanic cauterly to the removal of growths from the larynx also deserves mention. By this means a wire loop can be instantly raised to a white heat after its introduction. The first suggestion for using this agent dates from Middledorpf, (19) of Breslau, in 1854, and it has since been extensively employed by Bruno, Voltolini, and others. Nor can this record be closed without allusion to the remarkable device of Carlo Labus, of Milan, viz., the electric laryngo-phantom. This is a model of the larynx, intended to educate the manual dexterity of the student in the intra-laryngeal operations. Should he, whilst introducing his forceps, &c., touch any part improperly before attaining the desired point, his object is instantly balked by a spontaneous closure of the apparatus, consequent on the completion of an electric circuit.

 (4) *Der Kehlkopf des Menschen*. Tübingen, 1878.  
 (5) *Recherches sur l'anatomie normale de la muqueuse de larynx*, Thèse de Paris, 1874.  
 (6) In 1863 Rheiner had said:—"The laryngeal mucous membrane possesses, as is sufficiently proved, nowhere a trace of a papillary body."—Virchow's *Archiv*, Bd. V., p. 661. In 1878, however, Luachka (*op. cit.*, p. 171) asserted the presence of papillae, though few in number, in some parts of the larynx. These, according to Coyne, were merely folds of the mucous membrane.

 (11) *Die Kehlkopfswindstucht*, Leipzig, 1878.  
 (12) Virchow who is a strong advocate for tuberculosis of the larynx has attempted to explain away the conflict of testimony by asserting that the laryngeal tubercle is so perishable that it "becomes caseous and forms a tumour." (*Die Krankheiten Geschwülste*, 1861, Bd. II., p. 644.) Whatever may occur in certain cases that it does "become caseous and form a tumour" is conclusively proved by Bokitsansky, Heinze, and others. Binfleisch, on the other hand, only believes in laryngeal tubercle through respect for Virchow, and that by a full development of the catarrhal process in the mucous glands (glandular laryngitis of Green) all the phenomena of laryngeal phthisis may be presented. Hence in climax he exclaims, "What further remains for tubercle to do?" (*Pathologische Gewebelehre*, 3te Aufl., Leipzig, 1873, p. 583.) Nevertheless he testifies to the usual presence of "round clusters of cells, about the size of a glandular acinus," which he accounts as a "pledge" for the connection of the disease with the tuberculosis.

## Clinical Records.

### NORTH-EASTERN HOSPITAL FOR CHILDREN, HACKNEY.

#### Case of Obstinate Pemphigus.

Under the care of DR. ARMAND SEMPLE.

A BOY, *æt.* 7, came under care on May 22, 1884, with the following history: For the last two months he had suffered from an eruption over the trunk. The "breaking out" is on the increase and not diminishing. It caused him considerable irritation, burning, and smart.

*On admission.*—The boy is well nourished and of healthy appearance. The whole of the trunk, including the buttocks, both ankles, and right elbow are covered by a vesicular—and in some places—bullous eruption; the greater part of this surface is covered with an eczematous eruption. The bullæ are not situated upon inflamed bases, but they give the idea of a scald being the cause. The eruption causes considerable irritation. The scalp is also in a condition of pustular eczema. There is no sign of scabies. There are no physical signs in the lungs, and the heart sounds are normal. The bowels are clear and the tongue is clean.

He was ordered the following:—

R Misturæ arsenicalis, ʒss. Ter die.  
 R Unguentum bituminis compositum.  
 Lotionem bituminis compositum.

May 29th.—There is a general improvement this morning. No fresh bullæ have appeared. The old scabs are clearing off. The back is almost clean. There are a few recent bullæ about the ankles.

R Liquoris arsenicalis, ℥vi. Ter die.

June 5th.—There is a great improvement to-day. No fresh bullæ have appeared. The trunk is absolutely clear from all eruption. There are a few scabs still about the ankles and the calf of the legs.

8th.—The body is quite clean, and there is no evidence of any fresh sores.

The temperature on admission was 99°, and did not ascend any higher up to June 8th. Upon this day he was discharged cured.

On July 17th he was re-admitted with a fresh crop of the pemphigoid eruption.

*State on Admission.*—The trunk is covered, especially over the abdomen, with pemphigoid scabs, which vary in size from a sixpence to a shilling. There are numerous bullæ. Both lower extremities are similarly covered. There are one or two bullæ over the abdomen, now purulent. There is marked pustular eczema of the head. Ordered—

R Ferri tartarati, gr. v.  
 Misturæ arsenicalis, ʒss. Ter die.

R Ung. hydrargyri ammoniati dilutum.

July 19th.—The boy on this day developed symptoms of arsenical poisoning, such as running at the eyes and nausea. The arsenical mixture was therefore omitted.

R Mist. salinæ, ʒij. Ter die.

22nd.—There are a few fresh purulent bullæ over the belly, the right knee, and right elbow. Ordered—

R Vaselininum.  
 Ung. hydrargyri oxidi dilutum.

The following mixture was now ordered—

R Mist. arsenicalis, ʒij.;  
 Mist. rubræ, ʒij. Ter die.

Aug. 7th.—There is a fresh sore over the sacrum, and another over the left instep. Ordered—

R Mist. sodæ oxidi, ʒss., t.d.s.  
 R Lot. acidi boracici.  
 Ung. hyd. ox. dil.

29th.—To-day the treatment was altered to—

R Mist. arsenicalis, ʒss., t.d.s.  
 Adde liq. arsenicalis ℥ij.

and  
 Lotio plumbi.

The eruption is gradually dying away, but now and then a fresh vesicle appears.

The temperature from the 17th July until September 11th, on which day he was discharged well, presented no peculiar features, with the exception that only once in July it ran up to 101°.

On the 18th day he returned to the out-patient department, with a new crop of vesicles on the face.

On the 25th they were more numerous.

On the 9th of October there were bullæ scattered over face, trunk, and lower extremities.

*On admission.*—The boy is not in the same healthy condition as when discharged. There are numerous bullæ about the size of a sixpence over the chin and forehead. Over the lower abdomen they are more numerous and larger, three or four of them are quite purulent. There are several bullæ over the legs and around the ankles, these contain a clear fluid, and are not purulent. The bases are red, and surrounded by an areola of slight inflammation. The pulmonary and cardiac signs are quite normal. Ordered—

R Liq. arsenicalis, ℥ij.;

Mist. arsenicalis, ℥ss. Ter die.

R Ung. hyd. oxid. flavi, and fish diet.

Oct. 16.—The spots have nearly all healed. No fresh bullæ or vesicles.

20th.—The sores have quite healed. The boy is now quite well.

On the 22nd he was discharged cured.

From October 9th until the 19th the temperature never exceeded 99°, except upon the 22nd, when it suddenly shot up to 100°.

On March 18th, 1885, he was admitted again.

*Present illness.*—The boy has been ill for about three months, previous to which time he was comparatively well, and had no signs of any skin disease, but since this time he has been very much out of health generally, his appetite has been bad, and there has been a good deal of wasting, he has been irritable, and indisposed to any exertion. The eruption has been coming on during the last three months. On admission the boy seemed very ill, and could not bear being moved about on account of the soreness of the skin. The temperature is 102°. Tongue is furred and dry. On all parts of the body there are numerous bullæ of various sizes, some as large as half-an-inch in diameter, others much smaller, and they are in all stages of development. Some are merely reddish raised spots with slight vesiculation, and the larger ones have large semi-transparent blisters a good deal raised above the cutis, and containing a quantity of serous fluid; others are covered with thick greenish crusts, from the bullæ having burst and the secretion dried up. Besides, being on various parts of the skin, there is one bulla about the size of a currant on the tip of the tongue.

March 18th.—Being very restless, and unable to sleep, he was ordered—

R Tr. opii, ℥iij.;

To be repeated in two hours if necessary.

Full diet. Wine, ℥iv.;

R Mist. arsenicalis, ℥ss., t.d.s.

Eruption dressed with—

Acid carbol, ℥xxx.;

Lin. calcis, ad. Oj.

Covered with cotton-wool.

April 15th.—The eruption has greatly improved, but occasionally there are some fresh bullæ. The arsenic has been gradually increased to ℥vij. of Fowler's solution.

20th.—The boy has greatly improved. The face is now almost clear, and the eruption is much less on the body and limbs. There are no signs of arsenical irritation.

24th.—The arsenic is reduced to ℥iij. of Fowler's solution, as it has begun to produce symptoms of irritation in the eyelids and stomach.

28th.—The eruption is on the whole a good deal better, but there is one fresh bulla to-day on the right cheek. Ordered—

R Ferri tart., gr. v., added to the mixture.

May 6th.—Arsenic omitted to-day, and he was given—

R Mist. quinine.

Vin ferri, aa ℥ij., t.d.s.

12th.—Full diet.

Wine, ℥iv.;

Ferri tart., gr. v.;

Liq. arsen., ℥iv.;

Aq. menth. pip., ad. ℥ss., t.d.s.

One fresh bulla to-day.

20th.—Mist. quinine, ℥ss., t.d.

27th.—There is a fresh crop of bullæ on all parts of the body; they are very numerous. Arsenical mixture (May 12) repeated.

29th.—Still fresh crops of bullæ. Medicine every six hours. Tr. opii, ℥iv. nocte sum.

June 6th.—Acid carbol, ℥j. ; }  
Lin. calcis, Oj. } Pro. app.

23rd.—He is still taking the arsenical mixture. There are no fresh spots during the last few days.

July 2nd.—He was discharged perfectly well, and has continued so up to the present time.

The temperature from March 18th until June 9th was as follows:—On March 18th it was 101.8°; ran down on March 24th to 97°, up again to 101° on 27th, and gradually fell to normal on April 8th. On April 21st it suddenly ran up to 103°, and fell again to normal on the 28th. On the 20th of May the arsenical treatment was again omitted, but as numerous fresh bullæ appeared on the 27th May, it was resumed. On May 28th the temperature again rose to 103°, but gradually sank to normal on June 9th.

## France.

[FROM OUR OWN CORRESPONDENT.]

THE SCIENCE CONGRESS held its session this year in the picturesque town of Grenoble, in the department of L'Isère. The city was decorated for the occasion, and the affluence of visitors was very large. At the opening of the Congress M. Verneuil, the president, made a remarkable speech on conservative surgery, which he advocated in the strongest terms, and criticised severely the *prurigo secandi* of certain surgeons. "Since we are about to make some confessions," said he, "let us avow that certain men at certain periods, and in certain countries, have operated a great deal too much, and in our days even the *prurigo secandi* is a sporadic disease, endemic and epidemic, of which the vaccine has not yet been found. Proof is not difficult to find to establish my case. In the seventeenth century transfusion was commenced, and became so much the rage that an edict of Parliament in 1668 was obliged to be passed to stop it. In the eighteenth century every man that fell on his head was trepanned on the slightest suspicion of having his skull cracked. During the wars which terminated the century, and at the commencement of the present, every limb broken by a shot was amputated. When I commenced my medical career tenotomy was all the fashion, tendons, ligaments, muscles, were cut in every possible part of every body. The subcutaneous method was the saddle for the horse; it was the operative panacea. Later on resection, or what I would call *resocomania*, began to be practised on a great scale, especially in England and Germany, it was by hundreds that some surgeons could count their resections. When one specialist operates all the specialists follow suit. When he cuts anything all his colleagues cut also, with a little variation perhaps in the section and in the instruments employed. If, by-and-bye, a museum of operative medicine should be established, immense show windows should be made to expose all the lithotomes, urethrotomes, hysterotomes, and other machines ending in *tomes*, comprising all the little nameless instruments destined to cut the strictures of the nasal canal, strictures which in all probability never existed, and if they did do not want to be cut. Gynæcology and ophthalmology vie with each other for the place of honour on this new kind of turf, but I believe in the triumph of the first named. In these last years has been created, independently of cauterisation, often useless, an operation of Emmet, an operation of Battey, one of Alexander, &c. Reviews and journals speak of them, and praise them so that if a gynæcologist be not able to produce one or two cases he risks to pass for a man of little merit. The facility with which certain methods of practising is spread is astonishing. I may cite amongst others the scraping (*raclage*) or rugination of cold abscesses. The

theory may be sustainable, but on reflection certain reserves might be made, especially if experience were called in testimony. But for that it would be necessary to wait a while, and that is just what the present generation cannot bring itself to do. And thus surgeons scrape, scrape, and scrape again, and if any do not scrape are declared behind the times, and often in scraping they penetrate into the rachidian canal, and although the operation may have given encouraging results (it is the usual expression) the patient goes to join his ancestors in a better world. My design not being to give you a night-mare to-night, or to set you trembling all over by cold shivers, I will note, in concluding, a mania of the present time which would in itself be innocent if it were not ridiculous. I speak of the application of the actual cautery. This practice replacing the fly blister, painting with iodine, or the mustard (means much more simple), is certainly a revulsive of some value. But there was a method which was very complicated, and which struck terror into the hearts of children, giving at the same time very little pleasure to the parents (thermo-cautery). He felt assured that if in the audience before him there was a hundred persons attacked with external affections, fifty of them at least were treated by the actual cautery. If it were said, and not without reason, perhaps that the operations already cited, were good and deserved to be continued, I would add that they were entirely too much abused, that is to say, surgeons have too much transfused, too much tenotomised, too much resected, worked too much in the small pelvis of the female, scraped too many cold abscesses, and passed too often the thermo-cautere on the skin. If proof were wanting I would simply remind you that in a great country like ours with 37,000,000 of inhabitants, not more than half a dozen transfusions and a dozen trepanations are practised in a year. In England, where resection was so much in vogue, that operation is now rarely practised; before now, oculists believed that iridectomy was essential to the success of operation for cataract, and to-day they are agreed to respect the iris, and the famous scraping now in fashion will certainly in three or four years be classed amongst the operations of the past. Every surgeon of good faith and good sense who will read, with attention, facts relative to operations recently introduced, will not fail to be struck with the large number which were useless and sterile. Great noise was made over extirpations of the larynx, pharynx, stomach, uterus, kidney, &c. How many patients were cured? How many were benefited? Hardly 10 per cent! I invite your attention to this simple manner of reasoning. Take 100 cases of a given disease at a certain period, the half have been subjected to an operation, twenty years later only the fourth part have been operated on, and thus twenty-five of the first series must have been superfluous. In conclusion, the professor advised that the title of specialist should not be tolerated any longer, and that every surgeon should modestly keep himself within the common whole (*giron*) of general practice.

### Translations.

#### BIOLOGICAL EXCERPTS.

TRANSLATED FOR THE *Medical Press and Circular*.

**INHIBITION IN EPILEPSY.**—It is well known, as Prof. Brown-Séquard has shown, that certain parts of the nervous system can, under particular conditions suspend the physiological properties of other organs or parts of the system. The abolition of the reflex movements

which occur after an attack of epilepsy seems to be the result of an inhibition of spinal reflectivity by the encephalus. On the other hand, the reflex activity is exaggerated in epileptic attacks which are symptomatic of cerebral lesion, and follow encephalic lesions. These exist in the body-zones where the irritation gives place, either to the production of convulsive attacks, or to their exaggeration where they exist already. It is the same in choreic movements. It is important from a practical point of view, to determine the points where the irritation provokes the production or exaggeration of convulsion in the patient, because in applying at these places a therapeutic counter-irritation there is more chance of improving the condition of the nervous centre.

**EXPERIMENTAL ARTHROPATHY.**—M. Bochefontaine and M. Lombroso having severed in a dog the posterior right root of the second pair of dorsal nerves of the hind limb, caused a crural paralysis of the right side and, at the end of a few days, an oedematous swelling of the articulation of the left elbow. The lesion being cured, the animal was killed, when an atrophy of the posterior cords, and a degeneration of the anterior lateral cords were discovered. The experimenters consider this analogous to the arthropathy of ataxic patients. M. Brown-Séquard in 1855 discovered that the section of several pairs of nerves in the dorsal region causes paralysis of motion in the *corresponding* posterior member, and loss of feeling in the *opposite* one. M. Laborde disputes the circumstances as regards the arthropathy of ataxic patients, and says that up to the present medullary lesion after dividing the posterior portion of the root nerves, has never been noticed, and the dog in question did not become ataxic.

**THE RESISTANCE OF THE ARTERIAL AND VEINOUS WALLS** has been tested by M. Grehant with the aid of Regnaud's free air manometre, twelve metres high. The carotid artery of a dog can support the weight of eleven atmospheres without breaking, veins are a little weaker, and the jugular can only bear five or six atmospheres. The healthy arteries of an old man can resist six atmospheres, but when irritated, the pressure borne is only that of three, the resistance is slightly greater on the vessels at the right side.

**SALICYLATE OF METHYL** has been proposed as a therapeutic agent to supersede salicylate of soda. It colours salts of iron violet, is insoluble in water, of a light yellow shade, and has an agreeable smell. It has been proved to have no effect on cold-blooded animals (the frog, &c.), except when it is applied in subcutaneous injections in large quantities at the same time as the animal is breathing air, charged with salicylate of methyl. The silver absorbed is partly distributed in the system, and partly discharged by respiration and the other forces of nature.

**COCAINE** only produces local analgesia by inhibition, it acts by the peripheric nerves on the nervous centres, which react on the local sensibility. In fact, two minutes after the injection of a certain quantity of cocaine on the larynx as after the projection of carbonic acid at this point, there is a cutaneous anæsthesia (generalised) which remains for several minutes, and an analgesia of different wounds on the body of the animal which remains until the next day. These wounds newly formed are on the contrary hyperalgesic.

**THE EXCITABILITY OF MOTOR AND SENSITIVE NERVES** is completely independent of their nutrition, motor nerves deprived of circulation for a greater part of their length keep up their action on the muscles. Excitability of nerves exists after death from 5 minutes to 4 hours, available according to a number of conditions yet unknown. The muscular contractions which exist almost always after death and are

quite distinct from the following rigidity of the corpse, depend also on dynamogenic or inhibitory actions.

**CHEMICAL COMPOSITION OF TEETH.**—In the teeth of adults there is 25 per cent. of organic matter, and 75 per cent. of mineral substances. In those of very young children 30 per cent. at least of organic matter, and 69 per cent. only of mineral, besides carbonate of chalk and magnesia, which greatly increase the vulnerability. The more iron there is in the permanent teeth the weaker they are. The resistance of the teeth ought to be greater in proportion to the silicate in their composition when it does not exceed 50 per cent. There is very little fluorine in teeth at present, although it is found in large quantities in fossil teeth.

**EXPERIMENTAL THERAPEUTICS.**—The vascular modifications produced by certain medicines on the system are not the only ones to be considered in therapeutics. The direct action of those substances on the muscular and nervous elements ought to be taken into consideration, because the influence of the irritant agents on the nervous system is not always proportional to the pain felt. Experience shows us that covering the skin with nitrate of silver, although inactive, has been able to cure neuralgia, and rapid cauterisations with a white-hot instrument, which is less painful than when only red-hot, can produce the resorption of any liquid discharge. Neuralgia can be cured, says M. Dumontpallier, by the irritation of similar parts on the opposite side of the person.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, SEPTEMBER 9, 1885.

### MEDICAL VOTES AND VOTERS.

WRITING recently anent the coming General Election, we asserted our opinion that every medical voter in the Kingdom should act firmly on the principle that he is a doctor first and a politician afterwards, and we recur to

this subject for the purpose of repeating our entreaties that our *confrères* will, as far as they can, exercise their suffrages in the coming struggle independently and thoughtfully, and will not be induced to follow blindly the whistle of party leaders who value them only as so many insignificant units in the grand total which is to raise themselves to power.

We think it necessary to repeat our urging on this point, because the work of political organisation has commenced, and the fussy nonentities who delight to make themselves conspicuous on such occasions are already engaged in airing their political enthusiasm and their insignificance by importuning voters for promises of support.

We ask our readers to turn a deaf ear to such bores, and not to forget that if they throw their votes into the political chasm they simply throw them away and divest themselves of any political power whatever, and that they may even do worse than this if they thoughtlessly give their countenance and support to candidates who may be—for aught they know—bitter enemies of the medical profession, or under political pledges to oppose medical interests in Parliament.

We do not for a moment assume to dictate a vote to any man, for we look upon the exercise of the suffrage as a matter of personal discretion and choice as much as religion or dress may be. But we have as much right to advise a principle as the political bluebottles of any party, and we ask the profession to grasp the influence which they rightly possess, and to use that influence for their own objects, making their allegiance to party subservient to their allegiance to themselves. In any one of the electoral divisions of London there may be, say, 150 medical voters out of a constituency of, say, 30,000, and the influence of these 150 voters, if split up amongst two or three candidates would be absolutely inappreciable; they would be, of course, civilly accepted as a sort of makeweight, but not regarded as entitling their gives to any consideration either on the hustings or afterwards. But if even 100 of the medical voters in such constituency were to cast their lot in with some one candidate whom they knew to be sound on medical questions they would at once create for themselves, in that constituency, an influence which sooner or later would make itself felt in the House—they would secure a representative who would think it worth his while to join hands with other representatives similarly elected to advise on medical questions, to attend in his place when amendments were to be moved or spoken to, and, in short, to do something in return for his medical votes and something to keep his medical constituents in good humour with him.

There may be some of our readers perhaps who doubt that there are any medical interests which need a representative voice in Parliament, or which at all compare in importance with the political controversies of the day. These are the sort of men who act on the principle that the whole first cause and purpose of a doctor is the getting of fees, and that it is hardly *comme il faut* for a doctor to be coloured by any opinions on any subject except those directly correlative with the earning of money by treating disease. While we feel that we need

not attempt to create in such minds any feeling of what we may call medical patriotism, we would suggest that such matters as the educational selection of the men who are to be our *confères* in the future—the protection of the public and ourselves from the inroads of quacks—the organisation of securities for the health of the people of our country—and the maintenance of the efficiency of our medical forces in time of war and peace are, even as matters of business and money, at least as well deserving of consideration as are such matters as the government of the Soudan or the disestablishment of the Scotch Church, and we think such voters will agree that the medical interests to which we have referred afford them as good a reason for giving an independent medical vote as can be afforded by the consideration that their fathers before them voted for party, that their club *confères* are of a given political colour, or that they are bored for their vote by some casual acquaintance.

We are, however, very sensible that our advice can be acted upon by individual voters only subject to their personal interests, and we know well that many medical men are so situated that they can only exercise a very limited discretion. In the greatest degree does this reservation apply to the provincial medical men, especially those holding public offices in Ireland, for these live under the rule of politicians who would crush without mercy the doctor who dared to publicly dissent from them or whom they knew to have failed to follow their call. To voters so situated we must only counsel discretion, and remind them that the ballot is secret, but we may suggest to them that when the pressure upon them of opposed political parties is so nearly equal as to embarrass them they will find no better way out of their difficulty than to avow their determination to vote for medical interests clear of all political influence whatever.

In University constituencies and amongst metropolitan practitioners, and generally throughout England, Wales, and Scotland, these reservations against independent voting do not apply, for in these constituencies the medical voter, as a rule, has nothing much either to gain or lose by currying favour with any party. Some of his *quondam* political club friends may tell him that he is a political outcast, while they secretly esteem him as a man of independence and courage, and think his future support all the better worth seeking, but, *en revanche*, he will at once acquire a political importance which, as one of the herd, he could never possess; and he will find himself free to act as his conscience bids him.

We trust that the time is coming when the 23,000 medical voters of Great Britain and Ireland will come to be a concrete power bound together in general principles, and acting, as far as possible, independently of the shibboleths of party.

We would rather leave the application of the principle which we have above advocated to our readers than advocate the claims of individual medical candidates, however strongly we may feel about their claims. In a constituency as in that of the Edinburgh and St. Andrews Universities, where Mr. Erichsen, the medical candidate, is equal in all personal qualifications, and infinitely the superior on medical grounds, there ought to be no

second thought in the mind of the medical voter. He should vote for the medical candidate, be he Whig, Tory, or Radical.

The same rule should apply in Dublin City if Dr. Lyons is a candidate, and in those constituencies for which Dr. Foster, of Birmingham, Dr. Farquharson, or any other sound medical candidate offers himself. There are other probable candidates, including Mr. Meldon, who, though not medical by profession, have earned the gratitude and support of the doctors, and should have it with unanimity. There may be other competitors, who, though nominally representatives of Medicine, are valueless as such, or who have sacrificed medical principles and interests to catch the votes of a party, and such claimants deserve no consideration at our hands. We only wish we could put into the hands of our readers a long list of honest, intelligent medical competitors, whether Tory, Whig, or Radical, and we would gladly use every influence to aid the return of every one of them.

#### THE POSITION OF THE C.D. ACTS.

THE near approach of the rhetorical period preliminary to a General Election suggests the propriety of reviewing the bases of future legislation in relation to questions which are of general interest to the medical profession; and prominent among these is the Contagious Diseases Act. It will be remembered that the House of Commons was some time ago surprised one night into affirming the theory that the time had arrived for suspending the operation of this measure, an opportunity of broaching the question in a thin house having been cleverly seized by the friends of infection. Subsequently to this manoeuvre, directions were issued from the Home Office to the various centres where the Acts were in force, to the effect that compulsory examination of suspected women should cease; and the result of this terribly mischievous proceeding has been to increase immeasurably the amount of infective venereal disease amidst the forces, and at the same time to multiply the number of prostitutes plying their trade where soldiers and sailors form their chief *clientèle*. One result, indeed, of the Commission of 1882 was to prove to demonstration that the Act operated most powerfully in reducing the number of women on the streets, one authority of unimpeachable integrity giving the reduction (Devonport) as from 2,000 to 600. But more important than the mere numerical decrease is the fact that, wherever the Act has been imposed it has had a most remarkable effect in limiting the number of young or child prostitutes at such centres, for whereas as many as eight or ten per cent. of the whole number of these unfortunates were, before the enforcement of the Act, under fifteen years of age, there were scarcely any girls of tender age to be found in these centres, at the time when the good that was being accomplished was suddenly put a stop to, on Mr. Stansfeld's motion. The testimony to this effect is overwhelming, and includes that of a great number of witnesses enjoying very exceptional opportunities for arriving at the conclusions they have formed. Dispassionately viewed the history of legislation directed to prevent widespread disease offers the most absolute proof of the beneficent nature of the measures formerly adopted to such

end; and the melancholy increase, not only in the ranks of affected men, but also in the number of women following prostitution as a means of existence, which has followed on the short-sighted policy of the syphilis protectionists, ought of itself to be a sufficiently awakening force to the wilfully blind.

The people, unfortunately, cannot judge for themselves the evil that is in their midst. They are led away by noisy demagogues and paid agents of the societies that thrive upon the proceeds of their propagandas; a few earnest men there doubtless are whose own spotless lives have little fitted them to grasp the vital consequences of their vehement support of principles advocated by greedy agitators for their own base ends. It should be the endeavour of the profession now, and as occasion offers, to correct the limited and erroneous views that are current on this subject, and, as far as possible, influence candidates for parliamentary honours in the direction of light respecting one of the most important questions capable of occupying public and senatorial attention.

#### FRENCH VIEWS OF ENGLISH MEDICAL CHARITIES.

LONDON has lately been visited by a commission delegated by the Paris Town Council and Assistance Publique to inspect and report on the metropolitan hospitals, with a view to ascertaining in what manner the principles of management adopted in the English institutions can be imitated with advantage in France. The delegates paid visits to all our larger hospitals, and as well to the workhouses and infirmaries. With the former they express themselves as immeasurably delighted, and have nothing but admiration for all that they saw in this connection; but they speak only in terms of condemnation of our workhouses, and declare that the treatment received by casual paupers would not be for a moment tolerated by our neighbours across the Channel.

What specially concerns us, however, is the criticism of our visitors respecting English hospitals, and arrangements for dealing with disease; and in this connection nothing is more striking than the unfeigned amazement with which the delegates witnessed the rapid transmission of persons stricken with infectious disease from their homes to the special fever hospitals allotted to such patients. In Paris, no special institution for this class of diseases exists; no ambulance service for immediate conveyance of persons seized with fever or small-pox; no central agency for carrying out the regulations relating to this particular branch of public police. Consequently the ease, speed, and efficiency of the English system fairly astonished the French Commission; and the result of their experience here will, it may be hoped, prove of use by urging on improvement of the Parisian deficiencies.

The evident anxiety shown in English hospitals to promote not only the cure, but also the comfort, of patients, created a marked impression, the delegates comparing the bare whitewashed and unfurnished wards of their own hospitals with the warm-looking, decorated and pleasant abodes for the sick to which they were introduced in London, much to the disadvantage of the former. In their opinion also the food supplied to English patients is superior to that enjoyed by inmates

of Parisian charities, not merely in quality and quantity, but, strange to say, in the matter of cooking as well. They contend, however, that French hospitals ought not to be compared with richly endowed and lavishly supported London institutions, to which they have no resemblance save in name, but rather to our workhouse infirmaries, both being municipal burdens, and both being designed for sick paupers. The comparison goes no further than this, for our visitors urge that it is thenceforth much in favour of the French institutions, which though vastly inferior to English hospitals, are far in advance of workhouses in this country.

It is agreeable to us to have our true hospital charities so flatteringly spoken of; and should the reflections engendered by the inspection our welcome visitors have made of them, result in assimilation to them of French institutions, it will be a subject of congratulation to us as well as to the French nation.

#### Notes on Current Topics.

##### "Spinning" in Asylums.

DERIVING no doubt his suggestion from Ruskin, Dr. Richardson, Medical Superintendent of the Isle of Man Asylum, has introduced into that institution the old and picturesque art of spinning. Two wheels which were obtained with some difficulty, are now in daily use there, and seem to give much pleasure to the old people by recalling early recollections of the cottage fireside. All the yarn needed for the asylum use is now furnished by home manufacture. The example set by Dr. Richardson will be speedily followed in other asylums, as spinning seems to be a kind of occupation well suited for asylum wards, being interesting without being laborious, and free from danger and eminently useful.

##### Poisoning from Domestic Medication.

THE dangers that attend the administration of medicine to children without medical advice are constantly being illustrated in the proceeding of coroners' courts; and there is only too much reason to conclude that a good deal of the evil result ensuing in this connection is attributable to the circulation among the masses of so-called popular guides to domestic medicine the number of which now in course of publication is considerable. A case in point occurred but a few days ago at a village called Rishton. Two children, daughters of an operative, twins, and but four weeks old, were suffering from an attack of diarrhoea, and the mother took upon herself to treat them under the circumstances. To this end she procured a quantity of poppy seeds, stewed them for some time, and then gave each child three spoonfuls of the decoction. The unfortunate infants naturally died within twenty-four hours, and at the inquests which followed a verdict was returned to the effect that the mother had, in ignorance of the consequences, administered poison to her offspring. The parents were greatly distressed at the mischance, and it is to be hoped that they will henceforth see the advantage of seeking medical aid when the condition of their offspring seems to demand the employment of medicine.

### Quinoline from Coal-Tar.

MR. PERKINS in an interesting paper on the history of Coal-Tar Colour Industry, tells us, "That there is a very remarkable new manufacture growing out of the coal-tar colour investigations, and this is the preparation of derivatives of quinoline as substitutes for quinine. Although much of his time has been devoted to the study of quinine itself, he has not succeeded in producing it artificially, neither has he discovered any new bodies which are thought to possess valuable medicinal properties. Nevertheless, the formation of quinoline must be regarded as a rather remarkable development from this industry, seeing that it is owing to experiments made for the artificial formation of quinine that it owes its foundation. So far as the colour-producing industry itself has gone it has now furnished not only all the colours of the rainbow, but also produced the more sombre colours, not the less useful, and colours possessing different properties which fit them for special uses.

### Poisonous Honey.

TREBIBOND has long been known to produce honey of a very doubtful and even poisonous nature, and it has been lately reported that a number of persons were poisoned and three have died from eating wild honey found to be contaminated with or giving evidence of containing gelsemium. It appears that shortly after having partaken of the honey they complained of giddiness and dimness of sight, and but for the prompt assistance they received the deaths might have been more numerous.

### Typhoid Outbreak at Ashford Schools.

A SERIOUS epidemic of typhoid fever has occurred at the West London district schools situate at Ashford, and the circumstances attending it are of the most instructive nature. At the first the children were the ones attacked, and no fewer than 263 cases of the disease have been under treatment since July 11, the mortality being a little over six per cent., or a total of 15. What is specially noteworthy, however, is that owing to the sudden strain thrown on the nursing staff by the occurrence, this was reinforced by the regular school and establishment officials, the majority of whom, it must be concluded, were necessarily ignorant of sick room routine duties, of these temporary assistants no less than seventeen contracted the disease, and in three cases with a fatal result; and this notwithstanding that every precaution is said to have been observed to prevent such a catastrophe. This remarkable experience suggests either that the nursing has been conducted under circumstances favourable to the continuance of the causes which first provoked the outbreak, or that those who are unaccustomed to attending the sick are unable to observe the precautions necessary to their own protection against infection. We anticipate, however, that this matter will be fully investigated in the official inquiry which will naturally ensue as to the origin of the epidemic. All the cases remaining under treatment are said to be doing well, and anxiety is no longer felt as to the spread of the fever.

### A New Microbe.

ACCORDING to the American papers the researches which Professor S. A. Forbes, of the Illinois State College, has instituted into the cause of the terrible mortality recently prevailing among fresh-water fish in some parts of the American continent, have been rewarded with complete success. The report that he has just submitted on the subject shows that the disease is due to a minute spherical microbe or germ whose diameter is only about the 1-25,000 part of an inch. This germ he discovered in the liver and kidneys of the diseased fish; there it forms abscesses, which ultimately destroy the cells of these organs, and therewith the life of the fish. Professor Forbes says that there are various species of this germ, the different varieties of which cause specific diseases, such as fevers, and especially small-pox, chicken-pox, hog-cholera, and so forth. The case which more particularly prompted him to undertake the investigation was the extraordinary mortality among the perch and other fish of Lake Mandatta, Wisconsin, where the fish have, for some time past, been dying in enormous quantities.

### A Centenarian Scientist.

M. M. E. CHEVREUL, the veteran French chemist, is probably the first eminent scientist who has attained the ripe age of one hundred years without having had to intermit the labours which have gained for him a universal reputation in the world of learning. This patriarch of science attained his hundredth birthday a few days since, and the Royal Society of London has in him one of its most honoured and aged members, he having been elected a foreign associate of the society so long ago as 1826. Chevreul was born August 31, 1786, and his active work as a chemist was begun when he was seventeen years old, since which time, it may be said, that his life has been constantly passed in accumulating and imparting knowledge, and in making discoveries which have been largely influential in forwarding the progress of scientific chemistry, and in promoting its application to the arts. The recognitions showered upon him have been deservedly numerous and valuable, and have emanated from all quarters where respect for learning is exhibited. Chevreul was appointed Professor of Chemistry at the celebrated Gobelins' manufactory in 1824.

### Curved Bacilli in Air and Water.

In the present state of confusion which exists as to the exact rôle which Koch's comma bacillus plays in cholera, any information on the subject of curved bacilli is of interest. M. J. Hericourt finds that curved bacilli, of the same type as the cholera bacillus, are present in all waters, no matter what their source. The constant presence of these organisms can only be explained by supposing the existence of their germs in the air, in which they are present in the spore condition. Neutral bouillon and potatoes were sterilised and inoculated with dust from various places, and many curved bacilli developed in all the cultivations. They showed all the described forms—commas, curves, omega, S, spirals, &c. Intestinal dejecta in simple diarrhoea, dysentery, and typhoid fever, broncho-pulmonary secretions in all diseases of the lungs, pus ex-

posed to the air, the saliva of healthy and sick persons, were all found to contain curved bacteria, often in much greater number than other forms of bacteria. Collected first on bouillon or cooked potato, and then cultivated on nutrient jelly, these curved bacilli form rounded colonies with separated edges, composed of highly refractive granules. These colonies, kept at 20°—22° C., grow in the jelly and liquefy it, producing colonies of the shape of a gloved finger.

#### Rapid Passage of a Needle through the Body.

DR. J. P. DUGAN reports an interesting case in the *Cincinnati Lancet and Clinic*, in which a needle swallowed by a child, twenty-two months old, was passed *per anum* thirty-five hours afterwards. The infant was seated in its mother's lap while the latter was sewing, and managed to secure and place in its mouth unnoticed a threaded needle one and three-eighths of an inch long. The mother's attention being attracted to her child by its "gagging," she perceived the end of a piece of cotton hanging from its mouth, and drawing it forth, unsuspecting that it was threaded in a needle, the instrument remained behind and passed down the infant's throat. Dr. Dugan ordered that as much solid food as possible should be given, in order to keep the needle from contact with the intestinal walls; and the result was as stated above. The child did not suffer any inconvenience, and has been unaffected since by the occurrence.

#### Microbe of Yellow Fever.

MESSEURS. FREIRE and REBOURGEON having cultivated in bouillon of 38° C. micrococci obtained from the blood of a patient who had died of yellow fever, minute hyaline micrococci were found about one-quarter the size of the blood-corpuscles; larger cells resembling epithelial cells out of which micrococci were produced were also found. Under cultivation the micrococci went through all these stages: the lowermost layers were black, and exhibited, like the black cells found in the dejections, the reaction of ptomain. The dead black remains of these organisms were seen to act pathogenetically by the formation of ptomain.

#### Skeleton Tracheotomy Tube.

It has been often a subject of reflection to surgeons performing tracheotomy that the tube in ordinary use is a clumsy and cumbersome instrument, and that it occupies an amount of space that is altogether out of proportion to the necessities of the cases in which it is employed. Dr. E. T. Williams proposes to remedy the disadvantages connected with it by substituting for it a skeleton instrument, a description of which appears in the *Boston Medical and Surgical Journal*. It consists of two parallel blades or branches bent to the curve of a medium-sized tracheotomy tube, for insertion into the trachea. These branches are grooved on the inside like a tube, and convex on the outside. The upper rectangular portion lies flat upon the neck, and is secured by tapes in the same manner as an ordinary tube. The tracheal branches can be adjusted to any width, and so adapted to any size of trachea, by means of a screw arrangement

in the rectangular or external portion of the appliance; and when inserted in the trachea the apparatus is at once accurately and firmly fixed in position. This tube is a great improvement on the ordinary so-called "split" instruments at present in use, and is capable of being made by any mechanical instrument-maker.

#### Surgeons and Anatomy.

IN Pirogoff's Memoirs, now appearing in the *Wiener Med. Zeitung*, instances of the disregard or forgetfulness of anatomical details by leading German surgeons are given which sound somewhat strange to English ears. Neither Rust, nor Graefe, nor Dieffenbach knew anatomy. Rust once said very naively, in a lecture on Chopart's operation: "I have forgotten what the two bones there are called—the one convex, like a fist, the other concave in the joint; from these two bones the anterior part of the foot is separated." Graefe was in the habit of inviting Schlemm, the professor of anatomy, to great operations, and to inquire during the course of it, "Does not an arterial stem or branch run through there?" Dieffenbach simply ignored anatomy, and made merry over the situations of arteries. He considered the fear of wounding the epigastric artery in herniotomy to be a useless sensation. He used to say to his pupils of the same artery, "That is a phantom of the imagination." Dieffenbach was such a stranger to even the most superficial anatomical conceptions that he sent a piece cut out from the tongue of a stammerer to Johanne Müller, with the request that he, Professor Müller, would determine what muscle it was.

#### The Action of Lightning in Paralysis.

THE following singular clinical record is communicated by Dr. Kunze, of Halle, to the *Deutsche Med. Zeitung*, No. 69, 1885:—Frau Gutsbesitzer Winter, of Zaasch, aged 48, strong, powerful, of quick temperament, has had twelve children. Otherwise quite healthy, in the beginning of May she was attacked with phlebitis of the right leg. On May 20th she had so far recovered that she was able to perform her household duties with an india-rubber bandage round the part affected. On May 24th, after dinner, she had a stroke; speech was lost, the facial muscles on the right side were paralysed, also the right arm and foot. On the physician visiting her she complained of much pain in the head, the face was much reddened, complete right-sided paralysis was present. The only words she could pronounce, so as to be understood, were "ja," "nein," and "die, die." By June 8th there was no improvement in the speech; she could only raise the right arm by the aid of the left. The right foot showed improvement so far that she could walk with the help of her son, so that she was able to pass a few hours out of bed on the sofa. On June 8th, at 6 p.m., as the patient was sitting on the sofa in the sitting-room, a heavy thunderstorm passed over, the lightning struck the house, and also Frau Winter as she sat on the sofa, striking her on the paralysed side. The skin was reddened on the right shoulder and down the right side, and a burning, puckering sensation was complained of. After the depression caused by the fear had passed away and the patient was refreshed by rest she could raise the

right arm to the head without assistance. She could pronounce "ja" and "nein" distinctly, and also the name of her son Edmond, and the words Papa, Rheumatismus, Fuss, and several other words. During the first week after the lightning stroke, her condition manifestly improved, and on June 18th she could walk and raise the arm completely without assistance. A fortnight after, however, no further improvement was noted, and at the time of writing electricity was being applied daily.

#### Multifetal Pregnancy.

THE note from which the following is extracted was communicated by Dr. F. Poljakow to the *Medizinskoje Obozrenije*.—The Bauern M. Konakow, 27 years of age, has been married nine years, and has menstruated regularly every three weeks and six days since her fifteenth year. Pregnant six times, labour normal. The last menses were October 14th, 1884. In February this year she applied to a medical man, as the abdomen was increasing so much in size that respiration was impeded. It was ascertained that the uterus was considerably enlarged, of a rounded-oval form, with the fundus at the level of the scrobiculus cordis. To the right of the linea alba feeble cardiac sounds were heard; on the left small portions of a foetus could be felt. The birth of a dead child took place on February 28th, at 8 p.m.; a few minutes afterwards a second appeared, both breech presentations; and some minutes later, three more children, with their heads presenting. They were all born enveloped in amniotic sacs. The last four lived a short time. There was one placenta, weighing 585 grm., to the periphery of which the umbilical cords were attached. All the children were females, and corresponded in size to their period of growth, each weighing about 590 grm.] with the exception of the first, which weighed 934 grm., and was 41 cm. in length. Several fingers and toes were missing from the hands and feet.

DR. ALLEN E. DOUGLAS, of Warrenpoint, has been appointed a Justice of the Peace for County Down.

DR. RUBNER, of Munich, has been called to the Extraordinary Professorship of Hygiene in the University of Marburg.

It is rumoured that Professor Fuchs, of Luttich, will probably be appointed to succeed the late Prof. Jaeger in the Chair of Ophthalmic Surgery at Vienna.

STAFF SURGEON GAFFKY, the companion of Professor Koch in Egypt and India, has retired from active service in the Prussian Army, and been appointed a member of the Imperial Health Office.

As far as is known, the largest apothecary's establishment in Europe is that of Woldemar Ferrain, of Moscow, in which from 70 to 80 assistants are employed, and 700 to 800 prescriptions are daily dispensed.

DEPUTY SURGEON-GENERAL EDMUND GRESWOLD M'DOWELL, who was created a Companion of the Bath for his services as Principal Medical Officer in the

Soudan Campaign of 1884, has been appointed Principal Medical Officer on the Staff at Woolwich.

M. PASTEUR has lately been devoting himself to the perfection of the details of his scheme for protecting animals against the virus of hydrophobia. He is now satisfied that the measures to be taken are sufficiently settled for application to human beings, and on his return to Paris from his country seat in the Jura, the Professor will be prepared to put his theory to the test of practice.

### Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

CHOLERA SCARE AT LEITH.—Considerable excitement was occasioned in Leith last week by the arrival within port of a vessel from Spain with some suspicious cases on board; and as others had occurred during the voyage, the Customs authorities communicated with Dr. Williamson, medical officer of health, and Mr. Gilbert Archer, sanitary inspector, who at once proceeded on board the vessel, with the view of preventing the landing of either crew or cargo until both had been thoroughly overhauled. It was found that several of the crew were unwell, and though no cases of cholera had occurred, the symptoms were such as to lead the Customs officials to have the vessel detained in the Roads for prolonged medical inspection, and for instructions from the Government authorities in London. The crew consists of twenty men, and the pilot who brought the vessel up the Firth has not been permitted to land. As a precaution against any vessel from a cholera-infected port not having a clean bill of health, a boat and crew has been stationed by the Customs authorities at the end of the west pier. The Town Council have also written to the Dock Commission stating that, in view of the prevalence of cholera on the Continent, it is desirable that the Local Authority should be allowed to take possession of the hospital at the end of the west pier, in order that it may be put in a state of readiness for any emergency.

OUTBREAK OF SMALL-POX IN EDINBURGH.—At a meeting of the Public Health Committee of the Edinburgh Town Council, held on the 3rd inst., Dr. Littlejohn reported that a severe case of small-pox had occurred in the city, and the patient, a married woman, had been removed to the City Hospital. She had, it is believed, caught the infection while on a visit to some friends at Hartlepool. The apartment in which she is being treated has been completely isolated, and care is being taken to watch the health of the neighbours with whom the patient had been in contact since her return from England.

EDINBURGH.—HEALTH STATISTICS.—The mortality in Edinburgh for the week ending with Saturday, the 29th ult., was 72, and the death-rate 15 per 1,000. There were 13 deaths under one year, and 16 above sixty years. Diseases of the chest accounted for at least 25 deaths, and zymotic causes for 8, of which 5 were due to fever, 2 to diphtheria, and 1 to whooping-cough. The intimations for the week comprised—Fever, 21; diphtheria, 2; scarlatina, 16; and measles, 26.

EDINBURGH COTTAGE HOSPITAL FOR WOMEN AND CHILDREN.—A small portion of the premises in Grouse Street, Fountainbridge, used as the Edinburgh Provident Dispensary for Women and Children, is in course of being converted into a Cottage Hospital in connection with the

institution, and will soon be in readiness to receive patients. It is now about seven years since the dispensary was opened. From time to time a considerable number of cases have arisen which required the aid of careful nursing, good food, and quietude of order to bring them to a successful termination, and in such instances it has been necessary to draft off the patients in one or other of the public hospitals in the city. With a view of overcoming this difficulty, efforts were made sometime ago to add a few beds to the dispensary with a view of completing the treatment in connection with the institution of such patients as required surgical operations or continuous daily care. These efforts have been successful, and the hospital, containing half-a-dozen beds, will be opened in the course of a very short time.

## Literature.

### SELECTED MONOGRAPHS. (a)

THIS Society has in the present volume made a new departure by giving us, in one volume, three monographs on different medical subjects. It may be assumed that these papers are much above the average in merit, else they would not have been published as we now find them. The first, on Albuminuria, we would call a very elaborate essay. It gives the various forms in which albumen is excreted—albumen as a constituent of normal urine—the dependence of albuminuria upon alterations in the blood pressure, &c., and then in an appendix two contributions—1st, to the Theory of Urinary Secretion, and 2nd, the Hygienic Treatment of Albuminuria.

Whoever has had to deal with cases of albumen in the urine cannot fail to have been struck with the fact that this substance exists in the urine under a great variety of circumstances, which the reader will find detailed in the essay before us. For ourselves, we have long divided these cases into two great classes, those in which there is no evidence whatever of organic disease of the kidney, and those in which there are such evidences. The former of these afford a variety of circumstances, into which, however, we cannot enter here, but in which there is no organic disease. The state of the digestive powers, and as a corollary from this the state of the blood, seems to us to go a long way in explaining the occurrence of albumen. We know that a very slight attack of indigestion may lead to the appearance of albumen in the urine. Hence the treatment which causes the dyspepsia will also cause the albumen to disappear. Hence also an explanation of the fact that certain medicines cure albuminuria, such as iron, hydriodate of potash, gallic acid, &c., and they do so by curing the dyspepsia. But there is another aspect of this question which to us appears most important; nor are we sure that we have seen it noticed in any work, even the one before us. We mean where a certain amount of organic disease of the kidney exists, leading to the presence of albumen in the urine. In this state there is nothing more common than for dyspepsia causing albuminuria to be superadded, and then the state is one of functional combined with organic disease, the albumen being much increased. Here, again, treatment frequently removes the albumen due to functional derangement; whilst that due to organic disease will of course remain. We believe this view of the subject worthy of especial attention, though we cannot enter into it further here. To this paper is appended a lecture by the author on the Hygienic Treatment of Albuminuria, in which a strict regulation of the diet is enforced. The use of egg albumen is strictly prohibited, whilst a moderate amount of animal food is enjoined, and also vegetables. The functions of the skin are to be specially attended to, and a suitable climate for the patient to dwell in. Even supposing, however, that these several points are all carried out, the author cautions his readers from expecting much from the plan.

The second essay, on the Nature of Typhus and Typhoid Fevers, need not detain us long. At the time it was written

(a) "Selected Monographs: comprising Albuminuria in Health and Disease, by Dr. H. Senator; Some Considerations on the Nature and Pathology of Typhus and Typhoid Fever, by the late Alexander F. Stewart, M.D.; Movable Kidney in Women, by Dr. Leopold Landau." London: The New Sydenham Society. 1884. Pp. 870.

(1840) it was a valuable addition to the knowledge of the day, and certainly helped to clear up the difficulties which then surrounded the question of the identity or non-identity of the two fevers. But since then additional papers and works have appeared which have eclipsed, as it were, Stewart's paper, which, it may be mentioned, was read before the Parisian Medical Society, and at the time attracted much notice. In considering the early history of the subject the paper before us cannot be overlooked.

The third and last essay in the volume is on Movable Kidney in Women, and is to us a very interesting one. It is not so long since some eminent men denied the possibility of such an occurrence. But accumulated facts, and more particularly those derived from post-mortem examinations, have proved beyond question that the state does occasionally exist, and in obscure cases of abdominal tumour ought not to be forgotten. The essay before us is very elaborate. At the same time some of the points discussed seem to us to be too much strained. Thus the reasons why the kidney should ever be displaced are very far-fetched. No one in the habit of opening the abdomen can fail to have been struck with the great—we were going to say endless—variety presented by the several organs contained within. Their relative position to each other varies much, whilst their attachments and the surroundings of the folds of the peritoneum, may be said to be never similar in any two subjects. Keeping these facts in mind, there is surely nothing strange in the fact that the kidney has sometimes longer attachments than ordinary, and hence the organ becomes a "floating kidney," which seems to us a very happy expression to give this state; and when in addition we recollect that the human frame, and more particularly in females, is liable to become relaxed, and all the tissues flabby, we can understand why the position of the kidney becomes "movable," and why the expression "in women" is used, for this sex is much more liable to it than the other. One point in the essay strikes us as strange; we mean the question being discussed whether the right or the left kidney is the lowest in the abdomen. When we read this we began to question ourselves, and ask, had our memory failed, or was it not certain that the right is nearly always the lowest down? And this has been attributed to the position of the liver. We believe there is no doubt whatever on the point, and our wonder is it was ever discussed.

A question of more interest, as it appears to us, is why the right kidney is so much more frequently displaced, or rather movable, than the left. Our author gives several causes; amongst these are the absorption of fat from round the kidney, leaving the organ as it were loose in its capsule. But this cause, it is obvious, should apply to both organs, which it assuredly does not. Again, women who have had many children are stated by the author to be very subject to this condition of the kidney. But granting this cause as a general one, and the pendulous belly resulting, it does not show why the right kidney is by much the most frequently movable. In connection with frequent parturitions, the displacement of the organs of the pelvis cannot be overlooked, as giving a possible tendency to the dragging down of the kidneys. But neither here does it appear to us that such a cause should influence one kidney more than the other; and in truth we are puzzled to advance any plausible cause for the fact.

The chapter on Hydronephrosis as a consequence of movable kidney is one of much interest, but we can only refer to it here, as also to the chapters on Diagnosis and Treatment. Our author is against any operative proceedings, such as removal of the organ, in these cases, and we must say we go entirely with him. He describes, too, a particular form of staves, which he states are sufficient in themselves to relieve the distressing symptoms of the affection.

On the whole, whilst not agreeing with the author on every point he advances, and particularly as to the etiology of the affection, we consider this essay a very valuable one, and well worthy of perusal.

### CHEYNE'S ANTISEPTIC TREATMENT OF WOUNDS. (c)

WE welcome this manual, not only as a trustworthy guide to the practice of antiseptic surgery, but as being a more or less complete *résumé* of the different methods in vogue at

(c) "Manual of the Antiseptic Treatment of Wounds for Students and Practitioners." By W. Watson Cheyne, M.B., F.R.C.S., Assistant Surgeon to King's Coll. Hospital, &c. London: Smith, Elder, and Co.

home and abroad. It is, as it states to be, a manual for students and practitioners. Details so essential for the success of aseptic surgery are carefully and thoughtfully given, and illustrations are not spared to make the directions of the text plain and evident. Though the book throughout will repay careful perusal, yet one naturally turns immediately to see what Mr. Cheyne's views are on the necessity of the spray, and what explanations are given of the undoubted good results which the "open method" of treating wounds has lately achieved. In spite of Koch's researches, which dealt the most severe blow at the utility of the spray, Mr. Cheyne states that practically in his experience it is of the greatest value. Koch's experiments proved that while micrococci and other organisms without resistant spores are killed in a few seconds by carbolic acid, spores, on the other hand, can retain their vitality for a considerable time. As spores of bacilli are not found in the discharge from an aseptic wound, one must conclude either that they do not gain access to the wound, or if they do get in, the circumstances under which they are placed are unfavourable to their growth. If heat and moisture do cause the spores to germinate, they are then easily destroyed by the carbolic acid, but as a rule spores cannot germinate in the presence of carbolic acid, and are, on the other hand, soon destroyed by the action of the living tissues. On page 53 it is stated that "people are too apt to trust to the spray as sufficient." That washing out the wound with 1-40 carbolic lotion is considered a bad substitute for the spray is evident on p. 54, where it is stated: "This is a bad thing for the wound, because it irritates it, and may prevent healing by first intention or by causing a much larger quantity of discharge than usual; the gauze dressing may be so saturated with the discharge as to render it unable to prevent the spread of putrefaction inwards." With regard to the difficulty of employing the spray in country practice, the following sentence occurs on p. 105: "These methods—the use of catgut stitches and catgut drain, and the employment of a permanent deep dressing, together with the hints in cases where a drainage tube or non-observable stitches are employed—suffice to render the operator independent of a spray." Thus, though the spray can now and then be conscientiously dispensed with, yet other methods, as irrigation and distension, are not efficient substitutes, as the wounds are not only over-irritated, but there is a risk of carbolic acid poisoning. We do not find any mention of the sometimes dangerous cooling properties of the spray in prolonged operations or of the attempts made to provide dry antiseptic atmospheres. There is no attempt made to shirk an explanation of the success of the open method; it is stated that it has been looked upon as the antithesis of aseptic treatment, and yet when considered in the light of the true principles of antiseptic surgery it is found that it is really an advanced method of antiseptic treatment. "By freely exposing the discharge to air evaporation takes place, and the fluid becomes too concentrated to permit the growth of bacteria, while, at the same time, by supplying these organisms with plenty of oxygen, they have no necessity to break up the albuminous compounds in their search for oxygen, and thus, as shown by Pasteur, their fermenting power is diminished." Oxygen apparently not only interferes with the fermentative process, but actually destroys the bacteria which cause it. The fact of draughts preventing putrefaction is well known to housewives, who will keep, *e.g.*, grouse hanging for months in a current of cool air. But currents of cool air, in spite of the chain coccus of erysipelas, are also supposed by a considerable portion of the profession to be provocative of erysipelas. Erysipelas is not unknown even with strict antiseptic precautions. *A priori* one would think it would be of more frequent occurrence in the open method, but Mr. Cheyne does not give us any information on that head. The opening chapters are devoted to the processes of healing, description of micro-organisms, erysipelas, pyæmia, gangrene, &c., "matters (as stated in the preface) which were not ripe for discussion when my work on Antiseptic Surgery was written." These chapters are very lucidly written, and will be of much value to students preparing for the higher examinations. In looking through the chapter devoted to the substitutes for carbolic acid one cannot help being struck with the really slight advance in that direction since Lister originally described the method which goes by his name. *Salicylic acid* oxidises steel, and in the form of spray causes coughing and sneezing and adheres to the clothes. *Thymol* has been justly abandoned, as it does not prevent putrefac-

tion. *Acetate of alumina* has lately been recommended by Maas, as has also *eucalyptus oil* again by Schulz, of Bonn. The advantages of eucalyptus are, not only does the oil render the discharge pure as it passes over it, but also on account of its volatility bathes the part in an antiseptic vapour; it is stated to be a fairly trustworthy antiseptic, and can be used under circumstances where carbolic acid is apt to cause irritation, as in dressings on the scrotum or in patients whose skin is liable to be irritated by carbolic acid. On account, however, of the great volatility of the oil the gauze is very uncertain in quality, and is therefore not so safe as carbolic gauze. Severe irritation, eczema, and salivation have been noticed arising from *bichloride of mercury*; mixed with sand or coal ashes it is said to be a good powder for sprinkling over wounds. With regard to *iodoform*, it is stated, p. 121, that "it is not a powerful antiseptic, and is not now nearly so much employed as it was two or three years ago." "In the clinique of Max Schede and others who may be trusted to observe all the necessary precautions for antiseptic work, severe epidemics of erysipelas have occurred in wounds treated by iodoform, and they have for this reason and on account of its poisonous qualities given up its use." When a wound is already discharging, Mr. Cheyne does not like carbolic acid, because it so alters the granulations that they acquire many of the qualities of a recent wound as regards absorption. If carbolic acid (1-20) be injected into a wound once or twice a day it destroys the superficial granulation cells, and produces a thin slough in which bacteria develop, and from which it is difficult to dislodge them. Mr. Cheyne therefore recommends cleansing with chloride of lime (40 grs. to the oz.) and lint soaked in boracic lotion as a first dressing, followed on the next day by either salicylic, eucalyptus, or boracic ointments after the wound has been well washed with either acetate of alumina, sulphurous acid, chlorinated soda, or Hutchinson's alcoholic lead lotion. With regard to irrigation and immersion, the disadvantages are said to be the sodden state of the wound and the consequent œdematous condition of the granulations, the constant state of unrest of the wound and the inconveniences attending the application. Carbolic chromic catgut is still used for ligatures. With regard to sutures, waxed carbolic silk or silver wire is used. Ordinary silk steeped in carbolic lotion absorbs blood and serum, which putrefy in it, so the silk which was at first unirritating becomes very acrid, and causes inflammation in its vicinity. To avoid this, silk is steeped in a mixture of beeswax 9 parts and carbolic acid 1 part. The wax holds the carbolic acid and fills up to some extent its interstices, thus preventing it from becoming soaked with fluids. It must not be laid too long in the lotion before being used, else the threads become opened out.

Altogether we can strongly recommend Mr. Cheyne's book, and predict for it a rapid sale.

#### LOUIS PASTEUR: HIS LIFE AND LABOURS. (a)

THIS interesting autobiography of the great Frenchman we are told, "is a filial tribute written under the immediate supervision of M. Pasteur by his son-in-law M. Valéry Radot. It is certainly, as Professor Tyndall says, "the record of a life of extraordinary scientific ardour and success. The picture of a mind on which facts fall like germs upon a nutritive soil, and like germs so favoured undergo rapid increase and multiplication." No one who has followed Pasteur in his investigations will deny the truthfulness of Tyndall's picture, for certainly there is no part of the "infinitely little" which seems to have escaped his attention, and has not been enriched by his increasing scientific labours. This autobiography describes his more striking discoveries, beginning with the study of molecular physics, which were of considerable promise, when his attention became, as it were, accidentally diverted into another channel, and led him to the consideration of the phenomena of fermentation. Until then there had been various more or less erroneous explanations of this process, but no one had quite grasped the fact that it was due to the action of a living organism. "It matters little," he writes, "whether science makes of this vibrio a plant or an animal; it is a living organism endowed with motion which is a ferment,

(a) "Louis Pasteur: his Life and Labours." By his Son-in-law. Translated from the French by Lady Claud Hamilton. London: Longmans, Green, & Co. 1885.

and which lives without air." From this he appears to have deduced and traced the dependence of all fermentation on the presence of a living organism. Following up this question, Pasteur passed on to the study of acetification and the conversion of wine into vinegar by the action and growth of the *mycoderma aceti*. It was, however, well known to all chemists that vinegar, when exposed to air, not only deteriorates, but generates "little eel-like organisms which multiply with extraordinary rapidity, and not a barrel of vinegar manufactured by the New Orleans system, but what contains an alarming number." The significance, as well as the discovery of these animals, is due to the microscopical workers of this country, and manufacturers were made fully aware of the necessity of preventing and getting rid of these pests. It is unnecessary, did our space permit of it, to follow out the numerous investigations and humanitarian discoveries in which our French *confrère* has been for many years engaged. His labours and investigations are well known to, and their value fully recognised by, the medical profession, and we thoroughly endorse what Professor Tyndall has said in his introduction to this painstaking, careful translation by Lady Claud Hamilton, that in it "the reader is here presented with a record in which the verities of science are endowed with the interest of romance."

### Correspondence.

#### DR. BRADLEY'S CASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am not in a position to explain in public precisely what I meant by my letter, upon which you pass a certain amount of criticism in your issue of to-day, and it is clear that neither Mr. Martin nor Dr. Whittle quite understand it. If anyone requires an explanation I shall be glad to give it them *verbally*, but let me assure you that nothing in that letter in the least degree means, or is intended to mean, that I would not myself have voted for a verdict of not guilty in the case of Dr. Bradley. But it does assuredly mean that the evidence given at the trial, and which is upon Lord Coleridge's notes was such as made a verdict of guilty inevitable. If that evidence had been subjected to a cross-examination on the suggestions of a skilled expert a verdict of not guilty would have been returned. What I want to remove is the impression that Lord Coleridge was in any way influenced by animus against the prisoner.

Yours truly,

LAWSON TAIT.

Birmingham, Sept. 3.

#### THE INTERNATIONAL CONGRESS OF 1886.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I mail you a circular giving the true facts about the "International Medical Congress." The committee will meet September 3rd, and try to arrange all the present trouble in a satisfactory manner to the entire profession.

I can assure you, on behalf of the American Medical Association, that the Congress will be properly arranged, and all European visitors will be most cordially received.

Yours, &c.,

JOHN V. SHOEMAKER,

Sec. Committee of Arrangements.

Philadelphia, Aug. 21st.

[We are glad to publish the above letter, but, as our views on the subject of it have already been fully expressed in our columns, we shall reserve further comment until we have had an opportunity of perusing a report of the meeting referred to by Dr. Shoemaker.—ED.]

#### INOCULATION AGAINST CHOLERA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reply to Mr. J. O'Flanagan's letter in your issue of Aug. 26th, I regret that I seem to have failed to convey to him a satisfactory impression, that there exist facts and analogies which, when viewed in strict scientific and philosophical method, give us justification for seeking a prophylactic co-ordination of the system against cholera. Mr.

O'Flanagan must also excuse my saying that it does not follow because that I believe in vaccination against small-pox, or because I look forward toward a prophylaxis to cholera, that therefore, I must extend such methods to enteric fever, syphilis, &c. Nor can I, in such complex and obscure phenomena, as cholera, accept my own or any other student's views as "orthodox." The history of our knowledge, and in biology especially, shows that advances toward greater truths and generalisations have usually been unorthodox to the then-current opinions.

Twenty-five years ago, when I was in India, and making voyages with coolie emigrants from Calcutta to the West Indies, I was greatly possessed by the idea, that the outbreaks of cholera, which then often happened in the ships, soon after sailing, were due, not to any specific germ, or food, or drink, so much as to the *change* or *shock* which happened to the coolie's system, when taken from his warm natural-born conditions of health and life—say Bengal—to the sea. I held that the "shock" or *change* to the sea sometimes led to the natural evolution of cholera, just as I had seen the natural evolution of epidemic types of fever, in European emigrants, when they had passed from the southern tropic to high cold southern latitudes. The principle of management which flowed from such a hypothesis was a conserving one, of giving the people rest, warmth, &c., of conserving, as far as possible, their habituated "mode." But I had resolved to hypodermically inject with quinine and arsenic every one *not affected*, did cholera appear. Although I made eight such voyages, I was fortunate or unfortunate in having no epidemic of cholera in either of my ships, and was thus unable to put the hypothesis to the test. The practice is based on the ideas, that cholera *at certain periods of the system* is a natural evolution; that from the loss of the habituated environment of the living being, and the occurrence of "shock" or *change*, molecular vito-chemical actions happen, and "poisons" evolve, whose results are cholera. I sought to prevent the evolution of these (hypothetical) changes, by warmth, rest, &c.; and extending the hypothesis (as I was very familiar with the habit of taking quinine as prophylactic to fevers in tropical countries) and as I held that cholera was in "continuity," in its profounder nature, with the endemic fevers of Bengal, I ventured to suggest that we ought to seek a method of co-ordination against those first vito-molecular changes in the system which precipitate cholera.

The approximative hypotheses here indicated, imply (A) the absolute "continuity" of the inorganic and organic; (B) that what we call cholera are the results of vito-chemical changes (poisons) which have evolved in the system; (C) that at *certain times* a great variety of *changes* or *shocks* are enough to produce the decomposition of normal living matter, and to lead to the evolution of those vito-chemical bodies which produce cholera; (D) that the great cosmic Form of Evolution is ever acting, not only producing new species of animals and plants, but also new forms of disease; and that the potentiality of communicability may evolve in cholera under certain environment.

It would be easy to cite instances of the evolution of cholera from varied *changes* of environment: also instances of the ceasing of cholera from *changed* environment: but such instances must be familiar to readers of the literature of cholera, although different minds may interpret them by very different hypotheses.

I am very well aware that in what I have said above I have opened my flanks terribly! not the less, I hope and believe that my advance is on a right method.

Yours, &c.,

WILLIAM W. PEARSE, M.D.

Plymouth, Aug. 27.

#### "THE LONDON GAZETTE."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—What a grand thing it is to belong to the Medical Staff!

After all the toil, dangers, hardships. Such a splendid return. Four men specially mentioned. Three surgeons—majors and one surgeon. One poor fellow was actually promoted, but then he was dead, so that lost the State nothing. Grand, is it not? One surgeon was specially mentioned for distinguished service; but then he is alive. So it would be expensive to promote him!!! Now then, young surgeons, look sharp, or you may miss the chance of getting

into the glorious Medical Staff, where you will get kicks enough, but not many halfpennies. If you go in as private soldiers you may get the V.C. As medical officers you may be sure you will not get much beyond hard work and abuse. Perhaps our "only general" may do you the honour of giving you a good round of abuse if you forget to have fly fans or something you have no right to order.

For the whole staff at Suakin, one surgeon mentioned and not promoted: is it not grand?

Your obedient servant,

A NON-MILITARY SURGEON, AND THANK GOD FOR IT.

#### ADMINISTRATION OF NARCOTICS TO INFANTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the report of a case under the above heading by your "Northern Correspondent," in last issue, page 218, I find a statement that seems to require explanation. A child of five weeks dies after a dose of 5 drops of laudanum, given to allay pain and stop crying. A Dr. Crawford, who did not administer or prescribe the narcotic, but who saw the infant frequently between 10.30 a.m. on Saturday and 2 a.m. on Sunday, is examined by the Sheriff, who asks him, "At what age is it safe to give soothing syrup to a child?" To which the doctor replies, "I do not think it safe almost at any age under a year old." This in the first person. The report then goes on to make him say, now in the third person, "He should say *other homœopathic medicines* in bottles were also unsafe for mothers to give to children under a year old." Other homœopathic medicines! When was laudanum converted into a homœopathic medicine? and what sort of homœopathy is it to give a narcotic in order to allay pain? Hitherto we have understood that laudanum and its use to cause narcosis were characteristically allopathic; but if Dr. Crawford is correctly reported, he would seem to think that this was an illustration of homœopathic practice. It would be interesting to learn from Dr. Crawford what homœopathic medicines "in bottles" are "unsafe for mothers to give to children under a year old." Perhaps he will kindly inform us.

Yours truly,

R. E. DUDGEON.

53 Montagu Square, London, W.

#### COCAINE IN ASTHMA, HAY FEVER, &c.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A more extended use of *cocaine* makes me give a stronger opinion on its use in *hay fever*. Two per cent. solution to *nares*, *sp. as asthma* internally applied to tongue. One-tenth to one-half gr. in solution post nasal *catarrh*, applied on cotton-wool. Five per cent. morphia *craving alcoholism*. Nervous *debility*, from overwork, or any cause, it should get an extended use in "*spu asthma*." Cures tooth-ache, applied on cotton-wool. In *ophthalmic* practice, in *operations on eye it is invaluable*, as well as all small surgical operations, painted over part twenty per cent. solution. The best papers published on its use are those of E. Merck, Darmstadt, which can be had from H. Boyce, 72 Mark Lane, London, E.C., and a supplement to the Extra Pharmacopœia, Martindale, London, which no practitioner should be without.

I am, &c.,

T. J. GELSTON, M.D.

74 George Street, Limerick,  
July 24th, 1885.

P.S.—The *ovos pastiles* of Martindale are very good.

T. J. G.

**The Mortality of Foreign Cities.**—The annual death-rates per 1,000 in the principal foreign cities, according to the last weekly returns communicated to the Registrar-General, are as follow:—Calcutta 29, Bombay 26, Madras 39, Paris 22, Geneva 13, Brussels 26, Amsterdam 19, Rotterdam 21, The Hague 22, Copenhagen 16, Stockholm 21, Christiania 20, St. Petersburg 29, Berlin 28, Hamburg 25, Breslau 35, Munich 30, Vienna 20, Prague 31, Buda-Pesth 28, Rome 25, Venice 28, New York 35, Brooklyn 28, Philadelphia 22, and Baltimore 19.

**Vital Statistics.**—The deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 18.4 per 1,000 of their population, and were—Birkenhead 19, Birmingham 17, Blackburn 15, Bolton 13, Bradford 17, Brighton 20, Bristol 15, Cardiff 18, Derby 20, Dublin 20, Edinburgh 16, Glasgow 21, Halifax 16, Huddersfield 16, Hull 17, Leeds 18, Leicester 14, Liverpool 20, London 17, Manchester 21, Newcastle-on-Tyne 21, Norwich 14, Nottingham 15, Oldham 15, Plymouth 24, Portsmouth 23, Preston 27, Salford 24, Sheffield 18, Sunderland 22, Wolverhampton 21. The highest annual death-rates from diseases of the zymotic class in these towns were—From whooping-cough, 1.4 in Blackburn, 1.6 in Cardiff, and 1.7 in Derby; from measles, 1.7 in Derby; and from "fever," 1.2 in Sunderland, and 1.5 in Portsmouth. The death-rate from diarrhoea averaged 2.2 per 1,000, showing a further decline from the rates in recent weeks; it was, however, equal to 5.6 in Salford, 5.8 in Portsmouth, and 9.4 in Preston. Small-pox caused 15 deaths in London and its outer ring (exclusive of 4 in the Metropolitan Asylum Hospital Ships), and 1 in Manchester.

**Non-Arsenical Wall Hangings.**—Messrs. Wm. Woollams and Co., of High Street, near Manchester Square, W., ask us to announce that they have been awarded a Bronze Medal at the "Inventions" Exhibition for specimens of "embossed leather" and "Tergorine" lacquered and decorated for screens, wall hangings, &c. "Tergorine" is an artificial leather closely resembling real leather in appearance, non-poisonous and washable. Their stand is in the West Arcade of the Conservatory.

#### Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

#### DR. ROBERTS ON "FEEDING THE SICK."

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I desire with your permission to call attention to a point in Dr. Roberts' excellent introductory therapeutical lecture on "Feeding the Sick" at the recent meeting of the British Medical Association at Cardiff—a point which, even in men of the standing of Dr. Roberts, is apt to give rise to undesirable and, I doubt not, unjust comment. It occurs in connection with the subject of artificial digestion, where he alludes to a powder containing the pancreatic ferments prepared—and from the wording one would infer *solely* prepared—by some local chemist with whom Dr. Roberts appears peculiarly well acquainted.

Now I venture to suggest that men who hold a good position in our profession should be strictly on their guard to avoid even the slightest appearance of advertising any particular firm or unduly pushing their preparations, and it seems to me that Dr. Roberts has inadvertently done this in the present instance.

I am, Sir, yours, &c.,

IGNOTUS.

MR. CRANSWICK.—The diagnosis probably lies between syphilitic testis and tuberculous testis. The surface condition of the organ ought, however, to yield sufficient evidence of the nature of the growth, and especially when taken together with the patient's personal history and present condition. Hydrocele almost invariably accompanies syphilitic disease of the testis, and the epididymis is not affected at first.

T. T. L.—We cannot comply with your request at present, for the reason that our space is too much occupied with matter of more general interest than would be excited by the subject of your communication.

#### MEDICAL FEES IN BRAZIL.

A FEW weeks since we published a note on the fees charged in Brazil and the River Plate, which was disputed in one quarter. Confirmatory of our remarks a correspondent sends us the following advertisement from *La Nación*, of Buenos Ayres, which speaks for itself:—

"In view of the difficulties which, in many cases, the public experience in obtaining medical assistance during the night, Dr. Amuchastegui begs to announce a night service, with telephonic communication with (here the names of eight doctors are given). The surgery for this purpose will remain open during the whole of the night. N.B.—After eleven o'clock the fee charged for a visit will be 80 national dollars (\$80), payable in advance. For operations an extra charge."

Our correspondent adds: "Everybody who has resided in Buenos Ayres knows that it is almost a miracle to get a medical man to turn out at night "for any consideration," unless an arrangement has been previously made, as in midwifery cases. Truly, for medical men, the River Plate is as the Land of Goshen."

MR. H. E. R.—Burton would probably be the most desirable place to which to send your patient. We have known instances in which its thermal waters have had almost a specific effect after the exhaustion of almost every other common remedy. The principal characteristics of these waters are their constant and unvarying flow and temperature in summer and winter, the principal constituents, according to the most recent analyses, being chloride of sodium,

carbonate of lime, and carbonate of magnesia. On reference to the Medical Directory you will find the names and addresses of the principal members of the profession practising there.

DR. DAVIDSON.—We have the preparation under trial at the present moment. In a short time we expect to publish a report of the results gained with it.

DR. FETTER.—You are quite right; the accident is a rare one, and can only be produced as the result of indirect violence. It is most often observed in persons whose health has been broken down by a long course of intemperance, or by acquired syphilis.

ANTISEPTIC.—We have no doubt that, under the new Act, the owner of the property is fully liable for all the expenses incurred through the illnesses caused by imperfect drainage, and that a claim for compensation can also be maintained.

MR. MATHEWSON.—Do not settle on either hospital until you have made yourself acquainted, by personal observation, with the special advantages of each. You will find every facility afforded you to this end by the officials.

DR. MARLOW.—We are glad to have been the means of assisting your efforts, and shall esteem it a favour if you will keep us informed from time to time concerning the results that follow from them.

#### THE BRADLEY FUND—(FOURTH LIST)

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly acknowledge the enclosed additional list of subscriptions?

I remain, Sir, yours faithfully,

RICHARD JEFFREYS.

Fastwood House, Chesterfield, Sept. 2nd, 1885.

Sir George Burrows, Bt. . . . .	£5 5 0	Dr. A. C. F. Rabagliati . . . . .	£1 1 0

Mr. Frank T. Paul . . . . .	1 1 0		

CHANTICLEER.—We do not know any author who has written a special treatise on "Hybrids," but you would probably find what you want in Darwin's "Origin of Species" and "Plants and Animals under Domestication."

MR. BRINDLEY JAMES.—Declined, with thanks.

DR. ELWOOD LEW (Philadelphia).—We will test the splint on the first suitable case, and report the result. We do not, however, anticipate such a superiority over existing instruments as that claimed in the face of manifest objections.

AMATEUR.—*Anthea cereus*, *Bunodes ballii*, and *Sagartia bellii* yield to solvents a colouring matter resembling chlorofucin, and all the colouring matter, which in them shows this spectrum, is derived from the "yellow cells" (= symbiotic algae), which are abundantly present in their tentacles and elsewhere. It is not identical with any animal or plant chlorophyll, as is proved by adding reagents to its alcoholic solution. When "yellow cells" are present there appears to be a suppression of these colouring matters, which in other species are of respiratory use.

#### OPERATION DAYS AT THE LONDON HOSPITALS.

**MONDAY**—Hospital for Women, 3 p.m.—Metropolitan Free, 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Orthopedic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Mark's, 2 p.m.—Chelsea Hospital for Women, 2.30 p.m.

**TUESDAY**—Cancer Hospital, Brompton, 3 p.m.—Guy's 1.30 p.m.—St. Mark's, 9 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Westminster, 2 p.m.—West London, 3 p.m.

**WEDNESDAY**—Great Northern, 2 p.m.—London, 2 p.m.—Middlerey, 1 p.m.—National Orthopedic, 10 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Samaritan Free Hospital for Women and Children 2.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Mary's, 1.30 p.m.—St. Peter's, 2 p.m.—St. Thomas's, 1.30 p.m.—University College, 2 p.m.

**THURSDAY**—Central London Ophthalmic, 1 p.m.—Charing Cross, 2 p.m.—Hospital for Diseases of the Throat, 2 p.m.—Hospital for Women, 2 p.m.—London, 2 p.m.—North-west London, 2.30 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. George's, 1 p.m.—Chelsea Hospital for Women, 2 p.m.

**FRIDAY**—Central London Ophthalmic, 2 p.m.—East London Hospital for Children, 2 p.m.—Guy's, 1.30 p.m.—King's College, 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal South London Ophthalmic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Thomas's (Ophthalmic Department), 2 p.m.

**SATURDAY**—King's College, 1 p.m.—London, 2 p.m.—Royal Free 9 a.m. and 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic 1.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 1.30 p.m.

## Vacancies.

Abingdon Union.—Medical Officer. Salary, £130 per annum. Applications, with testimonials, to the Clerk, before September 19.

Birmingham General Dispensary.—Resident Surgeon. Salary, £150 per annum, with furnished rooms, &c. Applications, with testimonials, to the Secretary, on or before September 22.

Brighton and Hove Dispensary.—House Surgeon. Salary, £140 per annum, with furnished apartments, &c. Applications, with testimonials, to the Assistant Secretary, Brighton and Hove Dispensary, Queen's Road, Brighton, on or before October 5.

Chester General Infirmary.—Visiting Surgeon. Salary, £20 per annum, with residence, &c. Testimonials to the Chairman of the Board on or before September 18.

Ebbw Vale, Monmouthshire.—Surgeon (married) to take charge of an Ironworks and Colliery District. Salary, £550 per annum. Applications, with testimonials, to W. Dayson, Secretary, Doctors' Fund Committee, Ebbw Vale, Mon., on or before September 30.

Hartlepool Hospital.—House Surgeon. Salary, £100 a year, with board and lodging. Applications, with testimonials, to James Rawlings, Cliff Terrace, Hartlepool, before September 15.

Manchester Hospital for Consumption and Diseases of the Throat.—Medical Officer. Salary, £80 per annum, with board, &c. Applications, with testimonials, to the Hon. Sec. on or before Sept. 18.

Manchester Royal Infirmary.—Resident Surgical Officer. Salary, £150 per annum, with board and residence. Applications, with testimonials, to the Chairman of the Board, on or before Sept. 12.

Newport Infirmary and Dispensary.—House Surgeon. Salary, £100 per annum, with board, &c. Applications, with testimonials, to the Secretary not later than September 12.

Preston and County of Lancaster Royal Infirmary.—Senior House Surgeon. Salary, £100 per annum, with board, &c. Applications, with testimonials, to the Secretary, on or before September 11.

Sussex County Lunatic Asylum.—Junior Assistant Medical Officer. Salary, £100 per annum, with board, lodging, &c. Applications, with testimonials, to Dr. Williams, by September 16.

## Appointments.

BULLOCK, J. G. W., L.R.C.P. Ed., L.R.C.S.I., Medical Officer for the Rugby District and Workhouse of the Rugby Union.

CLARKE, J. M., B.A., M.B. Cantab., M.R.C.S., Resident House Physician to St. Thomas's Hospital.

CLEGG, J. H., M.R.C.S., L.S.A. Lond., Medical Officer of Health for the Stockton Urban Sanitary District.

CROWDY, F. D., M.B. Oxon., M.R.C.S., L.S.A. Lond., Assistant House Surgeon to St. Thomas's Hospital.

FOULKERTON, A. G. R., M.R.C.S., L.R.C.P. Lond., House Surgeon to the Royal Isle of Wight Infirmary, Ryde.

GREVILLE, F. A., L.R.C.P. Ed., L.R.C.P. Ed., Medical Officer for the Churchstunton District of the Taunton Union.

KERRHAW, M. A., M.B. Oxon., M.R.C.S., L.R.C.P. Ed., Resident Accoucher to St. Thomas's Hospital.

LAWSON, R., M.R.C.S., L.S.A. Lond., House Surgeon to St. Thomas's Hospital.

MATHEY, A., L.R.C.P., M.R.C.S., House Surgeon to the Creydon General Hospital.

MORISON, J. W., M.R.C.S., L.S.A. Lond., Medical Officer of Health for the Pembroke Union.

MURRAY, J. M. B., C.M. Aber., Assistant Surgeon to Her Majesty's Prison, Wakefield, Yorks.

RELTON, B., M.R.C.S., L.S.A. Lond., House Surgeon to St. Thomas's Hospital.

RITCHIE, K. D., M.R.C.S., L.S.A. Lond., Assistant House Physician to St. Thomas's Hospital.

ROBERTS, L., M.D., F.R.S.E., F.R.C.P. Lond., Obstetric Physician to the Manchester Royal Infirmary.

VOIGT, J. C., M.D. Ed., M.B. C.M. Ed., Resident Medical Officer and Visiting Surgeon to the Infirmary and Dispensary, Southport.

## Births.

ALLEN.—September 2, at 20 Regency Square, Elington, the wife of H. Marcus Allen, F.R.C.P. Edin., of a son.

HILL.—August 29, at 19 Thornhill Road, Barnsbury, the wife of Chas. H. Hill, M.D., of a son.

KESTEVER.—September 4, at 401 Holloway Road, N., the wife of Henry Ke-teen, M.R.C.S., of a daughter.

MCENERY.—August 30, at Semington House, Sherborne, Dorset, the wife of Dr. McEnery, of a daughter.

## Marriages.

CHADWICK—FISKE.—September 1, at St John the Baptist, Stockton, Wilts, George F. Chadwick, L.R.C.P. & S. Ed., of Codford and Mary, to Mary Elizabeth, eldest daughter of the Rev. E. W. Fiske, Rector of Stockton.

DIXEY—FERRINS.—September 3, at Little Aston, Staffordshire, Harry Edward Dixey, M.D., of Great Malvern, to Ellen Mary, youngest daughter of J. Dyson Ferrins, Esq., of Davenham Bank, Great Malvern.

HARBORD—WOOD.—September 2, at the Parish Church, Wem, Salop, Edward A. Harbord, M.R.C.S. Eng., L.R.C.P. Edin., of Newcastle-upon-Tyne, to Mary Lucy, only daughter of Thomas Wood, Esq., of Aston Park, Wem.

## Deaths.

HARRIS.—September 3, Francis Harris, M.D., of 24 Cavendish Square, London, and Lamberhurst, Kent, aged 65.

HEDLEY.—September 1, at Welford, Rugby, Charles Hedley, M.R.C.S. Eng., L.S.A. Lond.

MILLOCK.—August 23, J. Berry Mulock, M.D., of Bellair, King's Co.

TREVOR.—August 15, at Malta, Surgeon Robert Trevor, A.M.S., son of Mr. E. S. R. Trevor, Derwen, Welshpool.

### TWO CASES OF TETANUS.

By C. HANDFIELD JONES, M.B. Cantab., F.R.C.P.L., F.R.S.,  
Physician to St. Mary's Hospital.

*Idiopathic Tetanus of Great Severity—Treatment by Physostigma chiefly—Marked Improvement—Convalescence interrupted by Relapse about 16 days after the Drug was discontinued—On its resumption Amendment, going on to Recovery.*

CASE I.—J. S., æt. 23, house decorator, admitted April 16, 1884. Family history good. Has had no previous illness except once an injury to his side, which was not serious. Occasionally uses white lead, but never had any symptoms of poisoning by it. He was in his usual good health up to 10th inst., except that he had occasionally dull aching pains in his back for a day or two previously. On the evening of the 10th these pains increased, and he had a fall, the result, he says, of the pain, but did not hurt himself. He managed to walk about till the evening of the next day, when great stiffness of the lower limbs came on, accompanied by muscular tremors, and he had pain and stiffness in his back too. His abdomen became hard and contracted, and on the 12th his jaws became stiff, so that he could not open his mouth wide. Since that time he has been unable to take any solid food, but has lived on milk. The tetanus has continued up to the present time, April 17th, with occasional tremors in lower limbs, which shake his whole body; the back is generally arched when the tremors come on; both tetanic and clonic spasms cause him much pain. He has perspired freely ever since the muscular spasms have occurred. Bowels act fairly. He has not been in any way exposed to cold, or been in any unusual circumstances; has been working indoors at his occupation. When brought into the ward he lay stiffly extended on the couch. His face was flushed, drawn, and wore an anxious

expression. There was some rigidity about the muscles of the jaws; the lower jaw was retracted behind the upper; the tongue could only be partly protruded. The whole bed on which he lay vibrated; his lower limbs were in a state of tonic spasm, mingled at times with clonic; there was extreme rigidity of the quadriceps extensor muscles and of others; his legs were firmly extended, and could not be flexed without great difficulty; the reflexes were much exaggerated. The upper limbs were not affected, nor were the neck muscles appreciably, but he felt stiff about the neck. When clonic spasms supervened they were at once arrested by touching the soles of the feet, or by flexing the knees; but when opisthotonos came on the limbs were forcibly extended and tremors commenced at once. Abdominal muscles were tense and hard, speech was jerky, face and body generally bathed in sweat. No blue line on gums. Can swallow liquids, but not solid food. Tongue dry, thickly coated with yellow fur. Urine sp. gr. 1040, reddish, deposits urates. Pulse 96, strong, regular, full. Temp. 100.5. Heart and lung sounds fairly normal. Mental faculties quite unimpaired. Says he did not sleep at all on night of 16th; the spasms of the limbs were so acute, opisthotonos occurred every five minutes. Two hypodermic morphia injections, gr.  $\frac{1}{4}$  each, had no effect in inducing sleep or relieving pain.

On 17th I ordered an eserine disc, gr. 1-6th in each, to be given hypodermically 4tis horis, and ext. physostigmatis liquid, gr. 1-10th 3tis horis. He was placed apart in a corner of the ward and surrounded with screens, and directions were given that he should be kept very quiet. Brandy 4 oz. Relief seemed to be afforded by flexing his knees and placing a bolster beneath them. Some bloody urine was drawn off in evening.

18th.—Had three attacks of tremor in night, lasting each 2 to 3 minutes. Took milk well, and was very thirsty. Slept altogether 2½ to 3 hours, dozing, but pains of limbs woke him up. Gets much ease from straps carried from his feet to the head of bed. Pulse 120, regular, of fair force. Towards midnight spasms in

creased in severity; opisthotonos was very marked. At 3 a.m. some very severe spasms occurred, lasting longer than any previous. No action of bowels or bladder. Had two 20 gr. doses of chloral, four doses of mixture during day, and four eserine discs.

19th, 11 a.m.—Neck rather stiffer. Cannot protrude his tongue quite so well; jaws clenched firmly. Sweats profusely. Respiration 28. Occasionally has a kind of hiccup. Speech jerky. Pulse less strong, 112. No pain at epigastrium; recti muscles rigid, but abdomen moves in breathing. Spasms and opisthotonos very severe during day. Eserine discs omitted. Physostigma given in doses of 1-5th gr. 2dis h.

20th.—Spasms severe, varying in frequency from one to four or five in hour. Brandy increased on 18th to 6 oz.; to-day to 10 oz.

21st.—Better night than previous; spasms a little less frequent. Brandy seems to give much relief from pain. Passed urine naturally this morning. From 3 to 4 a.m. he had spasms frequently, bed vibrating greatly; he says himself that during this hour the spasms were continuous, without the slightest intermission. Seems very susceptible this morning; the least jar or sound tends to induce spasms. Pulse 116, rather weak. Respiration 36. Pulse at 4.30 p.m. 80, full.

22nd.—Better night, Spasms less frequent, though some were acute, and lasted some minutes. Bowels confined. Feels that the least thing would start the spasms. Abdomen moves well in breathing. Pulse strong, 120. Pupils rather dilated than contracted. Is able to read a little, but after a few minutes the page becomes blurred.

23rd.—Very fair night with two doses of chloral; spasms less frequent and powerful. Washing him did not induce spasms to-day as previously. Looks more comfortable. Has not the apprehensive expression in his face which he had yesterday. Later in day spasms became more frequent; a very powerful one occurred at 9.30 a.m.; it lasted some minutes; there was marked opisthotonos, risus sardonius, and some livid congestion of face. Atropiæ gr. 1-40 hypoderm.

24th.—A fairly good night. Spasms not so severe or frequent. Pulse 104, of good force. Bowels not open for several days. Urine, sp. gr. 1040. No albumen or deposit. Atropiæ gr. 1-30 hypoderm.

25th.—Had turpentine and ol. ricini in enema last evening; it returned without feces. Atropia gr. 1-30 has been injected thrice subcutaneously since 24th, but no marked relief from pain or rigidity has ensued. Had a worse night than he has had for last few days. Spasms were severe about midnight and 3 a.m. Chloral gave sleep for a little time. Does not seem worse this morning. Can swallow and breathe as well as before.

26th, 10.30 a.m.—Has just had a very severe spasm, induced by clerk's visit. Had much better night with one dose of chloral. Legs very rigid through night, but spasms not more severe than before, and not so frequent. Pulse of good force, 92. Respiration 32. Bowels not open. About 4.30 p.m. had four or five powerful spasms in an hour. Up to then had been more free than at any time before. Felt quite comfortable. Urinates easily.

28th.—Had fairly good day yesterday; was very free from spasms till towards evening. Slept fairly last night till 12, when he had a bad spasm. This morning early he was very restless, and had spasms frequently. Bowels still confined.

29th.—Had chloral without effect yester even. Between 12 and 1 a.m. had very severe spasms, in two of which emprosthotonos presented itself for the first time; the spasms this night were perhaps more severe than any he has yet had. Bowels opened fairly well at 2.30 a.m. After this spasms tended to decrease in frequency and force. No look of anxiety in face. Not sweating. Can flex his knees occasionally. Dose of physostigma raised to gr.  $\frac{1}{2}$  2dis horis.

30th.—Much better night. No severe spasms. Slept better and feels more refreshed than he has yet. Countenance brighter. Calf muscles almost natural; abdo-

minal are still very rigid; extensors of both thighs are lax; long flexors more contracted. Can semiflex legs himself. Can open mouth well. Little effect from aloes, gr. 4, last evening.

May 1st.—Had a fairly comfortable evening and night. Had very few spasms, and no bad ones. Affirms that muscles are much more rigid when he is asleep. He finds them rigid when he awakes. The fact may be that the muscles, becoming more rigid, awake him. Temperature normal for several days.

May 2nd.—Did not sleep much, but had only moderate spasms. Has a paler, anxious face this morning. Opens his mouth wider than he has done yet; had fish for dinner. At 2.15 p.m. his back was arched, so as to be four inches above the bed. Rectum was found choked up with feces half escaping from anus. At 3 p.m. was put in a bath at 110°, and remained in it a few minutes, but the rigidity of the muscles was not in the least lessened; rather seemed increased. His whole body was as rigid as a log of wood when he was raised up and removed from the bath. He felt comfortable in it and after. Repeat mist. 3tis. h.

3rd.—Good night; spasms not very frequent, last only half a minute now. All the abdominal muscles are still very hard; muscles of lower limbs pretty flaccid; has just flexed his knees himself. Breathes easily.

5th.—He feels and looks comfortable. Slept three or four hours without chloral. Can turn in bed pretty easily. Pulse 88; temp., p.m. 97, a.m. 98.

6th.—A good night without chloral; has had no spasms since 10 p.m. of 5th, but has crampy feelings in legs occasionally. Can flex either thigh directly on pelvis, but if he flexes the left leg the right is drawn aside, and vice versa.

7th.—Had one spasm in night, attended with aching of back, which awoke him from a sound sleep. It did not affect his legs so powerfully as before, but chiefly his back muscles. The sensation it produced was as if he was being cut with a knife.

9th.—No more spasms. Got out of bed, and sat in chair to-day. Appetite very good. Cannot get his heels to the ground, only his toes, in consequence of spasm of gastrocnemii. Pt. mist. 4tis. h. Brandy reduced to 5 oz.

12th.—Nights are fairly good. After sleeping an hour or two, is awoke by a feeling of cramp in his lower limbs, after keeping them in the same position for so long. Mouth cannot yet be fully opened. Abdomen moves fairly on deep inspiration. Pt. mist. *quater die*; ol. morrh, ʒj, *bis die*.

21st.—Abdominal walls much softer than at last date. Can flex his knees with less effort and both together. Has slept well last few nights with 30 grs. of paraldehyde, but not without. Can get out of bed himself, and to-day stood upon his feet, holding on to a chair.

26th.—Left leg feels stiffer than right; cannot be flexed so easily as the other when standing. In the warm bath can bend both knees as easily as ever. After walking gets clonic spasms in the right leg. These tremors cannot be arrested by touching the sole of the foot, as in the early period of the disease. He cannot bring his feet together while standing; they must be a foot apart. He cannot resist the effort of a strong arm to flex his right knee, and the endeavour produces a good deal of tremor. When first admitted the same arm had great difficulty in flexing knee. Physostigma mixture omitted about ten days ago. Ordered—Quinine, gr. v., t.d.; ext. hyoscy., gr. v., o.n.

June 2nd.—Gains strength in legs, but still has tremor.

5th.—This morning head was much retracted during sleep. Began to ail about 5 a.m.; got up, and was about for some time on the wet floor (probably fresh washed); then severe tremor of legs came on, which continued, with short intervals of quiet, for about two hours. At present the ankle-joints are tolerably mobile, but slight clonus can sometimes be elicited. Tickling the sole of

either foot produces tremor of both legs. Bowels open. Omitted quinine; resumed *mist. physostig. c. gr. 1-5th* in quarter dose.

7th.—Says he is better to-day, but pretty strong tremor of legs occurred spontaneously, shaking the bed as I sat by him. After the attacks of tremor his legs got very rigid for two or three minutes. In the night he had two or three slight attacks. Rept. *mist. 3tis. horis.*

9th.—Had one or two attacks of tremor in the night, but not painful ones. Abdomen not markedly rigid. No *opisthotonos* at any time since this relapse, but he feels pain in his back when tremors occur in his legs. Bowels have been constipated, but are fairly regular now. Tickling soles of feet causes very slight tremor. Before this relapse he noticed that any sudden noise—as the organ at chapel—brought on tremors in his legs.

16th.—Legs felt stiff in morning; he walks about, though his limbs are rather stiff.

23rd.—Is sometimes flushed in face. Can walk well, but has tremors occasionally affecting both legs, and to-day the right hand. As he sits on the side of his bed tremors occur rapidly, especially in left leg, and are not easily arrested by voluntary effort. Bowels never act without medicine. Sleeps well with *paraldehyde*. Omitted *physostigma*. *Succi conii, ʒij., t.d.*

26th.—After enema of a pint of cold water on the morning of the 24th he had severe tremors, and stiffness of jaws, arms, legs, and vocal muscles, lasting severely for half-an-hour. Yesterday he had an enema of warm water, which induced more severe spasms, especially in arms, but lasting only ten minutes. To-day seems better; has had slight tremors in right hand, none in lower limbs. Sweats only when tremors are present. *Papillæ* of tongue red, surface white. *Calomel, grs. ij., h.m.*

30th.—Improving, tremors lessening. Does not sleep without *paraldehyde*.

July 7th.—Tremors now are very slight. For last three or four weeks his eyes have been painful, especially in strong light, and have been blood shot. He cannot see the large figures at the bed heads on the opposite side of the ward, nor the name of the physician in large thick letters, unless he goes across the ward to within two feet of these objects. He can read the smallest size of Jager's types, but not rapidly, at about 8 inches. Eyes are most painful in mornings, get less so in a few hours. Before his present illness he could see objects plainly in the streets, but could not see remote objects as other persons did. Mr. Juler examined him the next day, and reported that *myopia* existed in each eye, about 6 D. There were typical *myopia crescents* at outside of each disc; no *optic neuritis*, or other fundus change. He was provided with suitable spectacles, and left hospital July 16th.

*Table of temperature.*—April 16th.—3 p.m. 100.5 deg. 17th.—3 a.m. 98.2 deg. 3 p.m. 100.3 deg. 18th.—3 a.m. 98.4 deg., 3 p.m. 100 deg. Thence on to May 10th, temp. was only twice over 99 deg., viz., on April 24th, 99 deg. 6 p.m., and on 26th, 99 deg. 2 a.m. From May 10th to June 7th, temp. only twice reached 99 deg. never exceeded it. From June 8th to June 24th temp. was almost invariably below 98 deg.

*Remarks.*—This case was one of great, though not extreme severity. For some time, there was ground for most serious apprehension that it might prove fatal; any notable increase in the violence of the spasms might have killed by arrest of the respiration. The age, and good physique of the patient, and his ability to swallow warded off death from *asthenia*. The lower limbs and back were the first parts to be affected, apparently about a day before the jaws. Nothing was discoverable in his previous condition which could account for the invasion of the malady. The disease was fully developed five or six days before his admission, but attained its acme about three or four days after. Its severity appeared to be materially controlled by *physostigma* given in frequent and tolerably large doses, though every now and then

paroxysms of formidable violence occurred, and made one fear lest worse should be in store. The abdominal muscles were more persistently rigid than any other, and next to these the long flexors of the thighs; the calf muscles were frequently lax while he lay in bed. The long muscles of the back, and the extensors of the lower limbs were the chief seat of the intercurrent spasms. The tonic spasms were frequently mingled with clonic, and the latter under the form of tremors were especially prominent in the earlier and later stages of the malady. *Emprosthotonos*—a rare symptom—occurred twice only. His statement, that his muscles were much more rigid during sleep, may have been to some extent correct, as he was sometimes awakened by the supervention of spasms, and we know that during sleep the reflex activity of the cord is less under the control of the higher inhibitory centres. Mr. Curling's case, however, indicates that the reverse obtains usually. Pain in the epigastrium said by writers to be scarcely ever absent was not mentioned by J. S., and, in fact, the tolerably free abdominal breathing showed that the diaphragm must have been comparatively exempt from painful spasm. The bowels were very torpid, but the bladder acted pretty fairly well. The intestinal paresis may have been caused by the excessive labour of the voluntary muscles, just as sometimes happens in pedestrian tours. Fever was almost absent, except to trifling amount on the three first nights of his stay in the hospital. The copious sweating which coincided with the muscular spasms and tremors may have contributed to lower the temperature, but as he was covered with bed clothes, it could not have been the chief cause of the *aprexia*. As profuse sweating is a common occurrence in tetanus, as well as high temperature, it is evident that the latter is by no means necessarily controlled by the former. In this, as in most other, instances *pyrexia* is essentially dependent on paresis of the heat regulating nerve centre, *vide Medical Times and Gazette, 1877, I.* The jerky quality of the speech was probably due to the expiratory muscles being unable to act steadily in consequence of their participation in the spasm. During the first two days the exaggeration of the excitability of the cord was markedly evidenced by the spasm being induced by the most trifling excitation, even the least jar or sound. Correspondingly the reflexes were exaggerated. A certain amount of benefit for a time was obtained by giving the feet a *point d'appui*, and affording some support to his flexed knees. The *rationale* of this is not very evident. A hot bath had no effect whatever in relaxing his rigid muscles; in fact, the general rigidity seemed to be increased, but this was perhaps due rather to the excitement caused by moving him into and out of the bath than to the hot water. A short trial was made of the continuous current to the spine, but it seemed rather prejudicial than otherwise, and was soon abandoned. Though the calf muscles were frequently lax while lying in bed, yet when he began to move about their undue contractile tendency was shown by his inability to put his heels on the floor. Even after the completion of the seventh week of his malady he had still very marked tremor in right leg, less in left, induced by walking or other exertion, and ceasing when he lay down. There was no *anclon* at this time. At the end of the eighth week a recurrence of disorder took place, marked by severe tremor of legs lasting at first with short intervals for two hours. Excitation of either sole caused tremor in both legs. This recurrence may have been due to walking that morning on a wet floor, or to the administering of quinine commenced nine days previously. It continued three or four weeks. This unusual event, and the very remarkable effects of cold and warm enemata as late as seventy days from the onset, show forcibly the tenacity of the morbid action, and its wide diffusion in the cord. It was over twelve weeks from the commencement before the tremors had practically ceased; he quitted the hospital about a week later. His legs a few days before he left were

unable to resist the force of a moderately powerful arm opposing endeavours to flex or extend them.

As to the treatment it may fairly be said that it was not mere expectant, and that the doses of physostigma were quite large enough to have been injurious in any ordinary state of the system. Dr. Ringer has given nearly three grains of the watery extract hourly for thirty-six hours with success. What I used was the spirituous extract of the B.P., probably a stronger preparation, as gr.  $\frac{1}{2}$  is spoken of as a maximum dose in ordinary cases. I entirely agree, however, with his recommendation that the drug should be commenced ("at the onset of the attack") and pushed sufficiently, its tendency to paralyze the heart, and the respiratory muscles should be counteracted by the simultaneous administration of wine or brandy. My patient took 10 ozs. of brandy daily for nearly three weeks without any intoxication being produced, a tolerably good indication that the stimulant was needed. The rate of the pulse was not markedly affected by the physostigma, it was probably more influenced by the occurrence of spasms. Atropia injected subcutaneously to the amount of gr. 1-10th, in twenty-four, hours was ineffective. Chloral and paraldehyde were useful to some extent in procuring sleep, but their influence cannot be rated highly.

CASE II.—*Injury to right temple—Tetanus sixteen or seventeen days after—Spasms became extremely violent four days after admission—Fatal terminat on two days later.*

E. H., set. 35, admitted November 30th, 1881. A dark complexioned, florid, well nourished, healthy looking woman. On November 7th she fell on the pavement and cut her right temple. On the 23rd or 24th pain began to radiate from the wound, especially over right malar region, where, to use her own words, it drew down her eye. The pain extended to the right lower jaw, and then to the left lower, going from there first to right and then to left side of neck. She compared the pain to a combination of stiff neck and sore throat. After her fall she caught cold, and the right side of her face became more or less swollen, but the swelling soon subsided.

On the 29th she found that she had difficulty in opening her mouth, and that attempts at moving jaws and swallowing gave her pain. The wound on the right temple was one-third inch long, and one-sixth inch deep. On evening of 30th her mouth was drawn, her jaws closed tightly, her voice strong, but articulation indistinct, swallowing was difficult and painful, no pain was felt except round the wound and in lower jaw and neck. On December 1st it was noted that the nostrils were dilated, the voice weak, thin, and querulous, the articulation impeded by viscid saliva, which tended to dribble out of the left corner of her mouth. The teeth were firmly clenched, and resisted attempts to separate them, but the closure of the jaws was much more absolute on the right than on the left. During the spasms the brows were knit and wrinkled, the angles of the mouth drawn up, the lips parted, the furrows from alae nasi to the corners of mouth deepened. The mouth and teeth were clogged with saliva, which she had much difficulty in swallowing and half choked her, and through which the air gurgled in respiration. There was no actual dyspnoea, though the breathing was shallow. The intervals between the spasms were about 15 minutes, and the paroxysms varied in intensity and duration. There was no retraction of head, nor any implication of the limbs. She could not lie down, and when raised in bed gave evidence of pain if the back of the head was not supported. Pain of rather vague character extended from the lower end of sternum to the interscapular region. The pain in her jaws she compares to a cord drawn tightly under her chin. The jaws can be separated two or three lines only, less on the right than on the left. Tongue and eye muscles were not implicated. Tenderness and pain were felt only at wound at the right mastoid process, under the right angle of the jaw, and over right malar bone. During the paroxysms

of pain she gets very hot and perspires. Breath foul. No sleep. Bowels confined. Urine, sp.g. 1023, no albumen. Pulse 125, rather weak, vessel rather small and hard, some pressure required to develope pulse. Temp. 98°4. Heart's apex beats in normal site, impulses strong, sounds distinct, first rather short and sharp. Good entry of air in both fronts, ribs throughout expand well. On admittance had morphia gr.  $\frac{1}{2}$ , subcut., potass. bromid. gr. 20, castor oil enema, enemata of beef jelly and brandy, 3ts horis.

December 1st.—Ext. physostigmatos liq. gr. 1-6th hypodermically 4ts h. Slept tolerably well after morphia. At first took nourishment with great difficulty, but later on swallowed 3 oz. milk.

2nd.—Slept fairly well, but swallowed worse. At 7 a.m. pains and spasms came on again. Eserine discs injected with relief after each. Feels weaker, has a gnawing pain at stomach, looks forward to the nutrient enemata for relief of this. Viscid mucus clogs her throat, and make her feel as if choking; cleansing the buccal cavity is very grateful. Pulse 126, soft, of fair force. Respiration 36. Bowels opened. Brandy 8 oz.

3rd.—Eserine discs given every two hours till 9 p.m., when pain was much relieved and pulse good. Injections of physostigma were then ordered *omni hora*, and an enema of peptonised meat, milk, and brandy 3ts horis. At 4 a.m. the house surgeon was called, and found her in great pain with thighs flexed on abdomen, abducted, and decidedly stiff, and now and then slight but unmistakable opisthotonos. Pains in jaw very great, no dyspnoea. Pulse small and rapid. Morphia, gr.  $\frac{1}{2}$ , was given at once, and in a few minutes she went off into a gentle sleep. No more eserine till 10 a.m., and no spasms. Mouth opened much better, and she felt much relief. Pulse 132, of tolerable force. Respiration 36. In afternoon bit her tongue, had twice stiffness and pain in legs.

4th.—Had considerable palpitation in night, relieved by hot stupes, was restless, and considerably worse after physostigma injection at 12.30. Several times complained of pain in legs. Says that when she sleeps her jaws relax, and directly she wakes they close with a snap, it was thus that she bit her tongue. Temp. last night 99°6, this morning 101. Face is fairly natural when spasm is absent, except at left (right?) eye and angle of mouth. Lies on her back with legs half flexed and abducted. Any voluntary effort of hers to move her legs, or slamming the door, or sitting up in bed, or manipulation by house surgeon, brings on tonic spasm; the calf muscles and quadriceps extensors become hard, pointing the toes, while the other muscles remain quite flaccid. Looks forward to her nutrient enema as wishfully as before. In forenoon had a choking fit so bad that she turned black in the face. For some time after her breathing was obstructed, and she kept on blowing out viscid saliva between her parted teeth. Sterno-mastoids quite flaccid, chest walls move well in respiration. Eserine discs given 2ts h., morphia gr.  $\frac{1}{2}$ , at 12.30 midnight, produced no sleep. Five ounces of brandy and milk taken in twelve hours by flexible tube passed through nares has relieved the gnawing sensation at the stomach. Chloral, gr. 30, in enema h.n.

5th.—Between 9 and 10 last night she was very bad, being constantly attacked by spasms and crying out. The abdomen and right leg seemed to suffer most. Got some relief from warm stupes. Till 5 a.m. was very restless, sleeping only a few minutes at a time. After that time she slept three hours consecutively. All nutrient enemata retained. Bowels well washed out. Once during the night she opened her mouth nearly an inch, but could not do it again. No curving of back noticed. Each time the spasm seized the abdominal muscles a small quantity of faeces was expelled into the bed. Food not taken so well. Pupils much contracted this morning. On waking complained of being very stiff all over. For the first time the spasms have extended to the arms. Has no pain in back, but has at epigastrium pain which is quite distinct from the gnawing of stomach, which

now does not distress her. Pulse 134, regular. Resp. 79. Abdomen moves in respiration. At 9 p.m. of 4th, morphia, gr.  $\frac{1}{4}$ , was given with eserine. At 10 p.m. eserine ordered o. h. At 2.40 of 5th I found her quite livid, and spluttering out viscid saliva and vomit-like matter. The jaws, abdomen, and legs were strongly tetanised. As the lividity passed off it gave place to hyperæmia. The left eye was closed, the left angle of the mouth drawn, inspiration was attended with a cry, and expiration with bulging of the cheeks. Resp. 56. Pulse 144. Atropiæ, gr. 1-60, was given, and two eserine discs at an interval of 15 minutes. At 9.50 p.m. she had a bad attack, lasting nearly ten minutes, at the end of which breathing stopped, and artificial respiration was employed for five minutes. Another bad attack occurred at 12.30, m.n., requiring the same remedy.

6th.—At 2 a.m. she had another attack, not quite so long, treated in the same way; it was followed by very rapid breathing. This attack, like the preceding, followed on her being fed by the mouth. Atropiæ, gr. 1-60, again administered. Great and violent shivering occurred for a minute or two, and delirium for five minutes, after which she became quieter till 2.30 a.m., sleeping at intervals. 2.55 a.m.—More crying out and short spasms; begged continually to be raised. 4 a.m.—Opisthotonos returning. Atropia, gr. 1-60, repeated. Pulse 160, small and fluttering. Respiration 60, very variable; some very shallow. After 4 a.m. the attacks became much more frequent, being ushered in by rapid and shallow breathing, which culminated in respiratory arrest, the face and lips becoming livid. Artificial respiration was performed till breathing was restored. After this no more food was given by mouth, and a nutrient enema was rejected during a spasm. At this time the pulse was not actually bad, but was getting weaker and more rapid. Half an hour before death the pulse began to get markedly weaker and more fluttering, and during the last hour seven hypodermic injections of brandy,  $\mathcal{M}_x$  were given. These had only a temporary effect, and she died quietly at 7 a.m. from asthenia.

*Table of Temperature.*—Dec. 1st.—98.4 deg. a.m.; 98.5 deg. p.m. 2nd.—98.6 deg. p.m. 3rd.—99.7 deg. a.m.; 99.6 deg. p.m. 4th.—101 deg. a.m.; 99.9 deg. p.m. 5th.—100 deg. a.m.

*Autopsy on Dec. 7th, thirty-three hours after death.*—Rigor mortis absent; hypostasis well marked. Greenish blue mottling on arms, abdomen, and legs. A small, somewhat triangular scar above the right orbit, about two inches from median line. Two small scars in left groin, and two on inner side of thigh, as if from ulcers. Cerebral arachnoid and pia mater exhibit pinkish discolouration. On section of brain an undue number of red points are seen. No hæmorrhages. Spinal dura mater shows engorged veins. In upper dorsal and cervical regions of cord the nervous tissue presented a diffuse brick-red colour. No hæmorrhage or other change visible to naked eye on section of cord. Each lung weighed 22 oz. Left was collapsed, and extremely congested, lower lobe to a large extent saturated with dark blood. No hæmorrhagic infarcts. Heart weighed 9 oz.; was flabby, its muscular tissue very soft, serous layers much stained with blood, valves normal. Liver weighed 43 oz., was flabby, pale on section. Spleen weighed 5 oz., rather large, congested, but firm. Each kidney weighed 4 oz.; they were extensively blood-stained, somewhat softer than normal. Uterus small; contained two fibroids. Fallopian tubes bound down by adhesions on both sides. The omentum is united to the right tube, at the extremity of which is a small cavity filled with caseous debris. Ovaries contain recent corpora lutea. No cysts.

*Microscopic Examination of Cord.*—Increase of leucocytes throughout its substance, especially in the grey matter. Vessels dilated, and containing red and pale corpuscles. Perivascular sheaths distinct, with scattered leucocytes between them and walls of vessels. In some

places leucocytes are seen packed around ganglion cells in space between them and matrix. No signs of miliary degeneration in either medulla or cord. On making a section of medulla below decussation of pyramids a spot of very distinct granular degeneration is seen in restiform body near surface. Pons shows no sign of disease. Cervical region: in posterior median fissure some fibrillated granular degeneration is seen, and the same is also present in other parts of the cord. Dorsal region: In upper part the ganglion cells appear degenerated, and merged in material of ground glass aspect in which nuclei are still distinct; in lower part right anterior cornu appears to have undergone partial liquefaction, not taking staining at all well. Sections of lower lobe of left lung showed masses of blood corpuscles in air-cells.

*Remarks.*—This case, though the symptoms set in late, more than a fortnight after the receipt of the injury, proved of great severity and ended fatally in thirteen days from the onset of the malady, and in less than six from the date of her admission. The intensity of the disorder was manifested, especially about the throat and jaws and face, where much pain was felt, swallowing being very difficult, and choking often imminent. The paroxysms of suffocation seemed to be rather dependent on spasm of the constrictors of the glottis than on a similar state of the muscles of the chest. Formation of viscid mucus in the throat contributed also materially to the embarrassment of respiration. The situation of the injury corresponded pretty closely with that of the most prominent symptoms; the irritation transmitted by the sensory nerves (the fifth) of the injured area would be readily communicated to the roots of the glosso-pharyngeal and the pharyngeal and laryngeal branches of the vagi. Yet it must be observed that more anatomical change was found in the dorsal portion of the cord than in the cervical. The remark is almost superfluous how far the alterations detected in the cord are from accounting for the phenomena of morbid action. The lesions are such as one would think likely to give rise to paralysis, not to intense spasm, and it seems difficult to come to any other conclusion than that their causative condition was invisible, but not so the results to which the over-action gave rise. As Dr. Maudsley has remarked of strychnia tetanus, we cannot see the exciting cause of the disorder, but the hyperæmia which the latter produces is patent enough. Tetanus is therefore a functional disorder. The pulmonary apoplexy, for such it really was, was due rather to vasal paresis and loss of retentivity induced by exhaustion than to congestion from impeded breathing. The latter would not have been confined to a portion of one lung. The treatment was quite inefficacious, though it was by no means feeble. Had it been commenced a week earlier it might have been successful. Each of the discs used contained gr. 1-8th of eserine, equivalent to 8 grains of Calabar bean. I doubt very much whether any other remedy of the same kind would have proved more beneficial. The disease being far advanced when she came under our care, support by alcohol and nutriment was imperatively called for, but its administration was difficult. It is noteworthy that the nutrient enemata relieved the gnawing at the stomach. The artificial respiration certainly prolonged life; she did not die from asphyxia, but from failure of the heart.

*The Mortality of Foreign Cities.*—The annual death-rates per 1,000 in the principal foreign cities, according to the last weekly returns communicated to the Registrar-General, are as follow:—Calcutta 26, Bombay 28, Madras 34, Paris 22, Geneva 16, Brussels 21, Amsterdam 17, Rotterdam 15, The Hague 19, Copenhagen 16, Stockholm 19, Christiania 27, St. Petersburg 30, Berlin 24, Hamburg 26, Dresden 25, Breslau 32, Munich 29, Vienna 23, Prague 31, Buda-Pesth 28, Rome 27, Venice 27, New York 24, Brooklyn 22, Philadelphia 25, and Baltimore 21.

THE  
NATURE AND TREATMENT OF GOUT.

By Dr. W. EBSTEIN,

Professor of Medicine and Director of the Medical Clinic at the  
University of Göttingen.

Non fingendum, aut excogitandum, sed invenendum quid Natura  
faciat aut ferat.—Bacon

(Continued from page 225.)

CHAPTER V.—(Continued.)

*Gout of the Human Subject from a Clinical Point of  
View.*

BEFORE I proceed to a more accurate description of these two forms of gout, I will make a few preliminary remarks respecting the etiology of them. In both forms equally when it develops primarily in the joint or in the kidney, that which sets up the disease process, the essentially active poison is uric acid.

But when uric acid injures the nutrition of the tissues, an accumulation of it must be present, if it cannot be accepted that the organs of the same individual are variously resistant at various times to an equal quantity of urates. A certain small quantity of uric acid compounds may circulate in our tissues and organs without injury to them, for uric acid is a product of normal tissue change, which, fabricated in adequate quantity and excreted by the kidneys, as far as we know, never, either at the place of its origin or in the organs for its excretion, produces symptoms that have any practical interest for the pathologist.

Bartels has indeed taken pains to prove that increased excretion of uric acid, the amount of which, as is known, varies in a state of health within certain not very wide limits, is *per se* without injurious consequences to the system. Whether this can be borne for any lengthened period without injury I shall not now discuss. In any case, gout does not arise in consequence of increased excretion of uric acid. All observers appear to be at one in this that the accumulation and stasis of uric acid in the system, in consequence of insufficient excretion of it, is a *conditio sine qua non* of gout. Whether the uric acid is at the same time formed in too great a quantity is a question on which up to the present there is no unanimity among investigators. Now one may acknowledge that here, as in other forms of stasis, the stasis may not only be general but local. The general stasis will take place when the excretory organs, the kidneys, act imperfectly, whilst the local stasis of uric acid will take place when the passage of the acid from the places of its formation, of which it must be assumed that there are many, into the fluids of the system, is disturbed, or when some hindrance is present to the movement of the juices containing uric acid. It is thus plain that local stases of uric acid may not only take place in various localities, but from various causes.

In the *first* case, *i.e.*, in that of *general uric acid accumulation, the kidney disease is primary, the accumulation of uric acid in the fluids and tissues secondary*. This manifests itself first in the kidneys, and not unfrequently death takes place in consequence of serious disease of the kidneys, before the consequences of general stasis of uric acid are otherwise manifest. In the *second* case, with localised accumulation of uric acid, the kidneys often remain healthy for a long time, sometimes permanently. The consequences of accumulation of uric acid are, for certain reasons to be inquired into, first made manifest in certain tissues. The typical representative of this form of gout, its most frequent mode of appearance, is *primary articular gout*, which will be first considered.

I.—PRIMARY ARTICULAR GOUT.

Pathogenesis, Symptoms, Consequences, and Complications.

Until a short time ago, it was generally accepted, and particularly on the authority of Garrod, that even in the milder form of gout, and in the earlier stages of it, the kidneys were

seriously implicated. Garrod believed that the onset of an attack of gout might be determined by the sudden cessation of the excretory power of the kidney. Such a one could be developed in consequence of traumatism, and even of mental disturbances. Garrod's statements, that should prove the diminution of the excreting power of the kidney, are not in a position to do this. He found that during an attack of gout the daily excretion of uric acid was not necessarily increased, but was often markedly diminished, but that the quantity of uric acid excreted on various days was very changeable. The maximum he met with was 0.48 grm., the mean of all his examinations was 0.21 grm. *pro die*. Unfortunately all these investigations relate to hospital patients only. I know of no observations in which the urine of members of the higher classes was examined during attacks of acute gout. Bartel's statements also relate to one infirm individual, the subject of gout, in whom, during the attacks, the excretion of uric acid was diminished to mere traces. In the case of chronic gout also Garrod found the quantity of uric acid much diminished, at various times very varyingly. Bartel once found 0.225 grm. per day in a patient in the chronic stage of gout. In weighing these facts it is to be borne in mind (1) that Neubauer affirms that in the normal condition the quantity of uric acid—which, like the quantity of urea, depends less on the food taken, than directly on the internal condition of the system—may vary very much, and may oscillate between 0.2 and 1 grm. in the twenty-four hours, as well as further, (2) that the local accumulation also, or, just as well, the diminished excretion, of the uric acid can be explained by the kidneys.
